VOLUME LX

MAY 1899 to OCTOBER 1899

*"To the solid ground*
*Of Nature trusts the mind which builds for aye."*—WORDSWORTH

London

MACMILLAN AND CO., LIMITED

NEW YORK: THE MACMILLAN COMPANY

Richard Clay and Sons, Limited,
london and bungay.

# INDEX

Abacus, Calculation by, Maurice d'Ocagne, 363
Abbe (Prof. Cleveland), the Height of the Aurora, 130; Meteorological Services in Russia, 299; Tornadoes, 328
Abbot (General H. J.), Climatology of Panama, 427
Abbott (A.), Progressive Lessons in Science, 543
Abelous (E.), Soluble Animal Ferment reductive of Nitrates, 264; Reducing Power of Extract of Animal Organs, 312
Abney (Captain W. de W., F.R.S.), Colour Sensations in Terms of Luminosity, 237
Aborigines of Australia, Cave Shelters and the, H. Ling Roth, 545
Abraham (H.), the Instantaneous Disappearance of the Kerr Phenomenon, 336
Abraham (M.), the Sterilising of Potable Water by Ozone, 24
Abt (A.), Magnetic Properties of Hematite, 540
Academies, the International Association of, 613
Acetylene, Velocity of Detonations of, Daniel Berthelot and H. Le Chatelier, 456
*Achlya Americana*, a Welsh Variety of, A. H. Trow, 37
Acids on Starch, the Action of, Dr. G. H. Morris, 608
Aclogue (A.), Faune de France, Mammifères, 410
Acoustics: Observations with Resonators for determining how Modulus of Decay is Affected, Dr. A. Pochettino, 17; Distant Sounds, W. F. Sinclair, 125; the Boyle Lecture on the Perception of Musical Tone, Prof. McKendrick, 163; Transverse Tones of Caoutchouc Threads, V. von Lang, 384; Beats given by Vibrating Strings, C. Maltézos, 456; the Audibility of Sound in Air, Rev. J. M. Bacon, 484
Acqua (Dr. F. dell'), Meat Consumption in Italy, 352
Addenbrooke (Mr.), Quadrant Electrometer for Application to Alternating Current Measurements, 70
Adie (R. H.), an Introduction to the Carbon Compounds, 271
Aerolite, the Bjurholm, 110
Aeronautics, Results of International Balloon Ascent, Dr. H. Hergesell, 66; the Report of the International Aeronautical Society, 183; Experiments on best forms of Curves for use with Flying Machines, A. A. Merrill, 257; Mathematical Investigation of Theoretical Vertical Movements of Free Balloon, Dr. Hergesell, 400; Death and Obituary Notice of Gaston Tissandier, 511; Death and Obituary Notice of Percy S. Pilcher, 546
Africa: Remarkable Meteorites at Mount Zomba, 85; the Harmattan Wind, Dr. von Danckelmann, 112; the Springbuck "Trek" in Cape Colony, C. Schreiner, 135; Eruptive Rocks of Cape Blanc, Algeria, and Duparc, E. Ritter, 144; Les Plantes Utiles du Sénégal, Le R. P. A. Sébire, J. M. Hillier, 148; Monkey Destruction on Gold Coast, R. Morley, 185; Mosquitoes and Malaria, Major Ronald Ross, 229, 398, 535, 574; Life History of the Parasites of Malaria, Major Ronald Ross, 322; the Cause and Prevention of Malaria, Major Ronald Ross, 357; West African Studies, Mary H. Kingsley, 243; Great and Small Game of Africa; an Account of the Distribution, Habits, and Natural History of the Sporting Mammals, with Personal Hunting Experiences, 270; Cyclopean Ruins in Portuguese Africa, Dr. Karl Peters, 280; Flora of Africa, 337; W. T. Thiselton-Dyer, F.R.S., 337; the Forests of the Sudan, Sir William Garstin, 401; the Vaï Language, M. Delafosse, 401; Dr. Livingstone's Tree, 425; the Extermination of Locusts by Fungus Inoculation, 426; Return of Major Ronald Ross, 574; Death and Obituary Notice of Dr. Oscar Baumann, 594; Death and Obituary Notice of Dr. J. W. Hicks, Bishop of Bloemfontein, 595; the Parent-Rock of the South African Diamond, Prof. T. G. Bonney, F.R.S., 620
Agamennone (G.), Methods of determining position of Epicentre in Distant Earthquakes, 46
Agriculture: Year-Book of the United States Department of Agriculture, 1898, 315; the West Indian Bulletin, 371; Agricultural Chemistry, Chimie végétale et agricole, M. Berthelot, 541; on the Chemical Effect on Agricultural Soils of the Salt Water Flood of November 29, 1897, on the East Coast, T. S. Dymond, 609; F. Hughes, 609; Official Report of the National Poultry Conference held at Reading in July 1899, 615
Air, the Audibility of Sound in, Rev. J. M. Bacon, 484
Air, Liquid, and the Liquefaction of Gases, T. O'Conor Sloane, 268
Aitken (R. G.), Double Star Catalogue, 354
Algebra, the Fundamental Principles of, Prof. Alexander Macfarlane, 515
Algæ, Iodine in Chlorophyll-containing, Armand Gautier, 336
Algae, Method of Preparing, for observation, 597
Algol Variable, the New, 354; New Variable of Algol Type, M. Ceraski, 114; the New Algol Variable in Cygnus, 232, 442, 538
Allegheny Observatory, the New, 260
Allen (Dr.), the Squirrels North of Mexico, 537
Allen (Dr. F. J.), the Nature and Origin of Life, 623
Allen (W. J.), the Destruction of Orange-tree Pests by Fumigation, 548
Alloys, Report of the Committee on the Heat of Combination of Metals in the Formation of, Prof. Vernon Harcourt, 586
Alpine Gardening, 6
Alps: Torsion Structure in the, Prof. Suess, Dr. Maria M. Ogilvie, 443
Aluminium Iodide, Explosion of, Prof. P. L. Narasu, 520
Amagat (E. H.), New Form of Relations $f(p, v, T) = 0$ for Fluids, 376
America: the Chief of the American Nautical Almanac, Prof. Wm. Harkness, 8; the Western Interior Coal-fields of America, H. F. Bain, 36; Bulletin of American Mathematical Society, 46, 117, 263, 308; American Journal of Mathematics, 90, 359; American Journal of Science, 117, 212, 383, 455, 516, 611; the Fresh-water Pearls of America, 150; Chapters on the Natural History of the United States, R. W. Shufeldt, 170; United States Geological Survey, 182; Recent Earth Movements of North American Lake Region, G. K. Gilbert, 182; "Amerind," a Suggested Designation for American Aborigines, 188; Impressions of America, T. C. Porter, 291; a Problem in American Anthropology, Prof. Frederic Ward Putnam, 451; American Association, 515
"Amerind," a Suggested Designation for American Aborigines, 188
Ames (J. P.), the Free Expansion of Gases, Memoirs by Gay-Lussac, Joule, and Joule and Thomson, 7
Ammon (Otto), Zur Anthropologie der Badener, 145
Amsterdam Academy of Sciences, 96, 216, 312
Anatomical Diagrams for the Use of Art Students, James M. Dunlop, 410
Anatomy: the *Calcar avis* common to all Mammalian Brains, Dr. Elliot Smith, 36; the Dog, its External and Internal Organisation, 435
Anderson (Dr. T. D.), Two New Variable Stars, 551

André (Ch.), a Remarkable Meteor, 408; Luminous Trains of Shooting Stars, 432
Andrews (C. W.), Geology of Christmas Island, 191
Animalium Index, C. Davies Sherborne, 174
Animals in Motion, E. Muybridge, 220
L'Année Biologique, 195
Anomalurus, Myology of, F. C. Parsons, 118
Antarctica: the Work of the Belgian Expedition, Lieut. Gerlache, 13; the Soundings of the *Belgica*, Henryk Arctowsky, 352; the Plans for Antarctic Exploration, 202; Government Grant in Aid of Antarctic Exploration, 256
Antelope, Larvæ from the Head of an, Richard Crawshay, 150; Walter F. H. Blandford, 150
Anthrax Bacillus, Enzyme Negativing Action of, R. Emmerich and O. Löw, 185
Anthropology: the Story of the British Race, John Munro, 52; the Origin of Religion, C. L. Henning, 135; Zur Anthropologie der Badener, Otto Ammon, 145; the Struggle between Peoples, Felix Regnault, 185; "Amerind" a Suggested Designation for American Aborigines, 188; Physical Measurements of Public Schoolboys, 198; the Winter Solstice Altars at Hano Pueblo, Dr. J. W. Fewkes, 258; the History of Mankind, Prof. Friedrich Ratzel, 269; Die Spiele der Menschen, Karl Groos, 363; Death and Obituary Notice of Dr. D. G. Brinton, 374; Three Crania from Swiss Lake Sites, E. Pitard, 401; the Vaï Language, M. Delafosse, 401; the Cambridge Anthropological Expedition to Torres Straits and Sarawak, Prof. Alfred C. Haddon, F.R.S., 413; the Negritos; the Distribution of the Negritos in the Phillipine Islands and Elsewhere, Dr. A. B. Meyer, Prof. A. C. Haddon, F.R.S., 433; a Problem in American Anthropology, Prof. Frederic Ward Putman, 451; Cave Shelters and the Aborigines of Tasmania, H. Ling Roth, 545
Anticyclones, Prevalence of, 366
Anti-Kathode, the Heating of the, in X-Ray Work, Dr. J. Macintyre, 101
Antiquities from the City of Benin, &c., in the British Museum, C. H. Read, O. M. Dalton, H. Ling Roth, 219
Ants, Harvesting, Prof. G. H. Bryan, F.R.S., 174
Aperçus de Taxinomie Générale, J.-P. Durand (de Gros), 489
Appell (M.), on Rolling Motion, 384
Applied Geology, J. V. Elsden, 148
Apse Line of *a* Geminorum, Motion of, A. Belopolsky, 377
Arachnidæ: Maternal Devotion of Spiders, Francis J. Rowbotham, 413
Archæology: Antiquities from the City of Benin in the British Museum, C. H. Read, O. M. Dalton, H. Ling Roth, 219; Cyclopean Ruins in Portuguese Africa, Dr. Karl Peters, 280; a Problem in American Anthropology, Prof. Frederic Ward Putnam, 451; Rock-Carving in Vancouver Island, 485
Arctica: the Glacial Phenomena of Spitzbergen, E. J. Garwood, 239; Death and Obituary Notice of Sir Alexander Armstrong, 257; Return of the Wellman Expedition, 399, 426; Bird Life in an Arctic Spring, the Diaries of Dan Meinertzhagen and R. P. Hornby, 542; Results of Lieutenant Peary's Explorations, 595
Arctowsky (Henryk), the Soundings of the *Belgica*, 352
Arithmetic: the New Science and Art of Arithmetic for the use of Schools, A. Sonnenschein and H. A. Nesbit, 7; a School Arithmetic, R. F. Macdonald, 7; the Arithmetic of Chemistry, John Waddell, 100
Arloing (S.), Influence of Manner of Introduction on Therapeutic Effects of Anti-Diphtheritic Serum, 215; Preventive Qualities of Blood Serum of Immunised Heifer against Contagious Peripneumonia in Cattle, 636
Armstrong (Sir Alexander), Death and Obituary Notice of, 257
Armstrong (H. E.), Laws governing Substitution in Benzenoid Compounds, 214; on Laws of Substitution especially in Benzenoid Compounds, 609; Symbiotic Fermentation, 609
Arrhenius (Prof.), Causes of Secular Variations of Temperature at Earth's Surface, 184
Arsonval (M. d'), Action of Gases on Caoutchouc, 239
Art Students, Anatomical Diagrams for the use of, James M. Dunlop, 410
Art of Topography, the, 101
Artificial Rearing of Young Sea-fish, W. Garstang, 631
Aschkinass (E.), Electric Oscillations and Moist Contacts, 117
Ashton (A. W.), Magnetic Hysteresis of Cobalt, 213
Asia: the Land of Rice, Taylor White, 8
*Asterionella Formosa*, G. C. Whipple and D. D. Jackson, 624
Astronomy: Scientific Worthies, Simon Newcomb, M. Loewy, 1; Our Astronomical Column, 18, 38, 63, 88, 114, 136, 161, 186, 207, 231, 260, 281, 301, 330, 354, 377, 402, 429, 442, 487, 513, 538, 551, 577, 597, 625; Second Washington Star Catalogue, 18; Spectra of Stars of Class III.*b*, Prof. W. C. Dunér, 18; Comet 1899*a* (Swift), 18, 38, 88, 114, 136, 161, 186, 260, 354; Prof. E. E. Barnard, 231; Prof. C. D. Perrine, 231; Comet 1898*a* (Swift), Herr H. Kreutz, 63; Tempel's Comet 1899*c* (1873 II.), 18, 38, 114, 161, 186, 207, 232, 260, 281, 301, 330; M. L. Schulhof, 63; Saturn's New Satellite, Prof. E. C. Pickering, 21; Primitive Constellations, R. Brown, jun., 31; on the Chemical Classification of the Stars, Sir Norman Lockyer, K.C.B., F.R.S., 52; on the Distribution of the Various Chemical Groups of Stars, Sir Norman Lockyer, K.C.B., F.R.S., 617; Death of P. T. Main, 60; Holmes' Comet 1899*d* (1892 III), 161, 232, 281, 354, 377, 402, 429, 442, 487, 513, 577, 597, 625; Return of Holmes' Comet (1892 III.), H. J. Zwiers, 63; Partial Eclipse of the Sun, June 7, 63; the Total Eclipse of the Sun, May 1900, C. H. Davis, 133; the Sun's Heat, Prof. T. J. J. See, 402; the Rotation of the Sun, C. A. Schultz Steinheil, 577; the Maintenance of Solar Energy, 615; Rotation Period of Mars, W. F. Denning, 64; Mars during Opposition 1898-1899, 330; New Star in Sagittarius, 88; Nova Sagittarii, 625; the New Algol Variable, 354; New Variable of Algol Type, M. Ceraski, 114; the New Algol Variable in Cygnus, 232, 442, 538; Two New Variable Stars, M. Luizet, 161; Dr. T. D. Anderson, 551; Southern Variable Stars, R. T. A. Innes, 513; Astronomical Occurrences in June, 114; in July, 207; in August, 301; in September, 429; in October, 551; Variable Radial Velocity of $\zeta$ Geminorum, 114; Motion of Apse Line of $\alpha$ Geminorum, A. Bélopolsky, 377; the Royal Observatory, Greenwich, 136; White Spot on Jupiter, Ph. Fauth, 161; Fifth Satellite of Jupiter, Prof. E. E. Barnard, 207; the Red Spot on Jupiter, W. F. Denning, 210; Opposition of Jupiter, 1899, 597; Spectra of Red Stars (Class III. *b*), Mr. Ellerman and Prof. G. E. Hale, 186; Spectra of Red Stars (Secchi's Type IV.) Messrs. G. E. Hale and F. Ellerman, 429; Oxygen in Atmosphere of Fixed Stars, David Gill, F.R.S., 190; a Short History of Astronomy, Arthur Berry, 196; Oxford University Observatory, 207; Cambridge Observatory, 208; Gravitation in Gaseous Nebulæ, F. E. Nipher, 212; Maxima of Mira, A. A. Nyland, 232; the Life of a Star, Prof. J. Perry, F.R.S., 247; Dr. T. J. J. See, 519; the New Allegheny Observatory, 260; Leeds Astronomical Society, 260; Theory of the Motion of the Moon, E. W. Brown, F.R.S., 260; the New Lunar Photographic Atlas, 491; Longitude from Moon Culminations, D. A. Pio, 538; Annals of the Astronomical Observatory of Harvard, 266; Dynamical Theory of Nebulæ, Dr. E. J. Wilczynski, 281; the Natal Observatory, E. Nevil, 281; Temperature changes in Yerkes Object-Glass, Prof. Barnard, 281; Stellar and Nebular Spectra with Concave Grating, 302; Photography of Nebulæ and Star Clusters, 330; Double Star Catalogue, R. G. Aitken, 354; Elements of Cometary Orbits, G. Fayet, 354; Mr. Tebbutt's Observatory, 377; Temperature in Gaseous Nebulæ, F. E. Nipher, 377; the Recent Perseid Meteoric Shower, W. F. Denning, 377; the Paris Observatory, 402; the Bulletin Astronomique, 402; Photometry of the Pleiades, Herrn G. Muller and P. Kempf, 429; the System of Sirius, Herr H. J. Zwiers, 429; Catalogue of Astronomical Instruments, Sir Howard Grubb, 430; Harvard College Observatory, Prof. Pickering, 442; Vanadium in Meteorites, M. B. Hasselberg, 487; Cordoba Photographs of Star-Clusters, 488; the Indian Eclipse, 1898, E.W. Maunder, 489; the Story of Eclipses, G. F. Chambers, 489; The Bulletin de la Societé Astr. de France, 513; New Spectroscopic Multiple Star, Prof. W. W. Campbell, 513; Stellar Parallax, Osten Bergstrand, 538; Precession Tables, Dr. Downing, 538; Histoire Abrégée de l'Astronomie, Ernest Lebon, 543; the Melbourne Observatory Annual Report, P. Barrachi, 551; Comet Giacobini (1899 E) 551, 577, 597; P. Chofardet, 612; the Polaris Multiple Star, Prof. W. W. Campbell, 577; Astronomical Camera Doublets, 578; Observation of Leonids, 578; the Coming Shower of Leonids, W. F. Denning, 592; Law Connecting Motions in Planetary

System, Ch. V. Zenger, 597 ; Orbit of Eros, Herr Hans Osten, 625 ; Strassburg Observatory, 625
*Astrosclera Willeyana*, J. J. Lister, 631
Athènes, Annales de l'Observatoire National d', publiées par Demetrius Eginitis, 266
Athens, Meteorology at, 157
Atkinson (E. H. de V.), Text-book of Practical Solid Geometry, 122
Atlantic Cable ; the Life Story of Sir Charles Tilston Bright : with which is Incorporated the Story of the Atlantic Cable and the first Telegraph to India, Edward Brailsford Bright and Charles Bright, 613
Atmospheric Railway, the South Devon, Sir Frederick Bramwell, 327-8
Atomic Weights, Proposal to Establish an International Committee on, Prof. Tilden, 609
Atoms, on the Existence of Masses Smaller than the, Prof. J. J. Thomson, M. Broca, Prof. Rücker, Sir Norman Lockyer, Prof. Oliver Lodge, 586
Auden (H. A.), the Synthesis of Camphoric Acid, 214
Auerbach (Felix), Kanon der Physik, 314
Aurora, the Height of the, Prof. Cleveland Abbe, 130
Australasian Association, the, 82
Australia : Meteorology of South Australia, Sir Charles Todd, 134 ; in the Australian Bush and on the Coast of the Coral Sea : being the Experiences and Observations of a Naturalist in Australia, New Guinea and the Moluccas, Richard Semon, 169
Ayrton (Mrs. W. S.), the Reason for the Hissing of the Electric Arc, 282, 302

Babes (V), Prevention and Cure of Toxic Epilepsy by Injection of Normal Nerve Substance, 312
Backhouse (T. W.), Remarkable Lightning Flashes, 520
Bacon (Rev. J. M.), the Audibility of Sound in Air, 484
Bacteriology : Bacteria and Tobacco, G. C. Nuttall, 159; Enzyme Negativing Action of Anthrax Bacillus, R. Emmerich and O. Löw, 185 ; a Polymorphous Bacterium, S. Hashimoto, 185 ; Malaria and Mosquitoes, Prof. Grassi, 157 ; Major Ronald Ross, 229, 398, 535, 574 ; Prof. Koch, 595 ; Life-History of the Parasites of Malaria, Major Ronald Ross, 322 ; the Cause and Prevention of Malaria, Major Ronald Ross, 357 ; Investigations on Mosquitoes and Malaria, Dr. Daniels, 333 ; the Present Position of the Investigation of the Malarial Parasite, 439 ; Investigation of the Malarial Parasite, 546 ; Action of Quinine on the Parasite of Malaria, Dr. D. L. Monaco and L. Panichi, 576 ; Bacteria, Dr. George Newman, F.R.S., Dr. A. C. Houston, 434
Bacoucea (M.), Prevention and Cure of Toxic Epilepsy by Injection of Normal Nerve Substance, 312
Baden, the Anthropology of, Otto Ammon, 145
Bailey (G. H.), Advanced Inorganic Chemistry, 76
Baillie (Charles William), Death and Obituary Notice of, 204
Bain (H. F.), the Western Interior Coal-field of America, 36
Baker (C. H.), a Gigantic Annual Plant, 485
Balance, Gravity, Quartz Thread, R. Threlfall and J. A. Pollock, 69
Balance, Gravity, a Portable, Profs. Threlfall and Pollock, 587
Balbiani (Prof.), Death of, 327 ; Obituary Notice of, 399
Baldwin (Prof. J. Mark), the Story of the Mind, 172 ; Heredity and Variation, 591
Balland (M.), Change of Flour-gluten with Age, 360
Balloons : Wireless Telegraphy between two, 278 ; Unmanned Balloon Ascent, 351 ; Mathematical Investigation of Theoretical Vertical Movements of a Free Balloon, Dr. Hergesell, 400
Bárcera (Mariano de la), Death of, 35
Barnard (Prof. E. E.), Fifth Satellite of Jupiter, 207 ; Comet, 1899 a (Swift), 231 ; Temperature Changes in Yerkes Object-glass, 281
Barnes (Prof. C. R.), Progress and Problems of Plant Physiology, 563
Barral (Et.), Preparation of Phenylic Chlorocarbonates, 240
Barrachi (P.), the Melbourne Observatory Annual Report, 551
Barrett (Prof. W. F., F.R.S.), Historical Note on Recalescence, 173 ; the Thermo-electric Properties of an Alloy Containing Iron 68·8 per cent., Nickel 25·0, Manganese 5·0, and Carbon 1·2, 586
Barton (Dr.), Criterion for Oscillatory Discharge of Condenser, 70
Basset (A. B., F.R.S.), Bessel's Functions, 101, 174
Bats and their Insect Prey, C. Oldham, 624
Baubigny (H.), the Separation of Traces of Bromine existing in Chlorides, 72 ; Separation and Estimation of Traces of Bromine in presence of large excess of Chlorides, 95 ; Estimation of Traces of Chlorine in presence of very large excess of Bromine, 143
Baumann (Dr. Oscar), Death and Obituary Notice, 594
Baxendell (J.), Self-recording Anemoscope, 215
Bay of Fundy, W. Bell Dawson, 161 ; Tides in the, Sir J. W. Dawson, F.R.S., 291 ; W. H. Wheeler, 461
Beasley (H. C.), Cast from Footprint in Stourton Trias, 143
Beattie (Prof. J. C.), Electrical Leakage from Charged Bodies, 95
Becquerel Rays, Profs. Elster and Geitel, 623, 635
Becquerel Rays and Magnetic Field, Profs. Elster and Geitel, 230
Beddard (Frank E., F.R.S.), a Note upon Phosphorescent Earthworms, 52
Bedeutung der Reize für Pathologie und Therapie im Lichte der Neuronlehre Die, De A. Goldschneider, 73
Bedford (F. P.), Gecko Cannibalism, 8
Bee-culture in United States, Frank Benton, 352
Beeton (Mary), Inheritance of Longevity in Man, 356
Békel (A.), Mixed Anhydrides of Formic Acid, 192
Belgian Antarctic Expedition, the Work of the, Lieut. Gerlache, 13 ; the Soundings of the *Belgica*, Henryk Arctowsky, 352
Bell (Ernest D.), Mammalian Longevity, 30
Belopolsky (A.), Motion of Apse Line of α Geminorum, 377
Beman (W. W.), New Plane and Solid Geometry, 517
Benham (Prof. Wm. Blaxland), the Development of the Tuatara, 79 ; the Skull of Hatteria, 567 ; Phosphorescent Earthworms, 591
Benin, Antiquities from the City of, in the British Museum, C. H. Read, O. M. Dalton, H. Ling Roth, 219
Benton (Frank), Bee Culture in United States, 352
Benzaldehyde, on the Action of Caustic Soda on, Dr. C. A. Kohn, 609 ; Dr. W. Trantom, 609
Benzenoid Compounds, on Laws of Substitution, especially in, Prof. Armstrong, 609
Bergens Museum, Report on Norwegian Marine Investigations, 1895–97, Dr. Johan Hjort, O. Nordgaard, and H. H. Gran, 313
Bergstrand (Osten), Stellar Parallax, 538
Berlin Tuberculosis Congress (1899), Dr. F. W. Tunnicliffe, 108, 154
Berry (Arthur), a Short History of Astronomy, 196
Berthelot (M.), the Formation of Alcohol by Plants, 167 ; Argon and its Combinations, 288 ; Combination of Sulphide of Carbon with Hydrogen and Nitrogen, 312 ; Ammoniacal Silver Nitrate, 384 ; Metallic Derivatives of Acetylene, 408 ; Reaction of Argon and Nitrogen with Mercury Alkyls, 408 ; Velocity of Detonations of Acetylene, 456 ; Chimie végétale et agricole, 541 ; Trimethylene, 564
Bertin (L. E.), Marine Boilers, 289
Bertrand (Gabriel), Properties of Dioxyacetone, 384
Bessel's Functions, A. B. Basset, F.R.S., 101, 174 ; Prof. A Gray, F.R.S., 149
Bevan (E. J.), Oxidation of Furfural by Hydrogen Peroxide, 118
Bicycle ; La Bicyclette, sa Construction et sa Forme, Dr. C. Bourlet, 77
Bidwell (Shelford, F.R.S.), Magnetic Strain in Bismuth, 222 ; Curiosities of Light and Sight, 389 ; Dark Lightning Flashes, 591
Billow Clouds, Wave or, 235
Biology : a Biological Aspect of Cancer, F. J. Faraday, 23 ; Obituary Notice of Charles Naudin, 58 ; Results of the Scientific Expedition to Sokotra, 116 ; L'Année Biologique, 195 ; Thatsachen und Auslegungen in Bezug auf Regeneration, August Weismann, 242 ; Die Methode der Variationsstatistik, Georg Duncker, 338 ; the Soluble Ferments and Fermentation, J. Reynolds Green, F.R.S., 361 ; the Living Organism, an Introduction to the Problems of Biology, Alfred Earl, 458 ; Death of Johannes Müller, Prof. Virchow, 595 ; the Nature and Origin of Life, Dr. F. J. Allen, 623 ; Marine Biology, Survey of Western English Channel, Walter Garstang, 157 ; an Account of the Deep Sea Ophiuroidea collected by the Royal Indian Marine Survey Ship *Investigator*, R. Koehler, 459
Birds : Cries and Calls of Wild Birds, C. A. Witchell, 171 ; Habits of the Cuckoo, Wm. H. Wilson, 175 ; an Illustrated

Manual of British Birds, Howard Saunders, 241 ; Bower-birds, A. J. Campbell, 275 ; Sedge-warblers Seizing Butterflies, Oswald H. Latter, 520 ; Bird Life in an Arctic Spring : the Diaries of Dan Meinertzhagen and R. P. Hornby, 542
Bismuth: Magnetic Strain in, Shelford Bidwell, F.R.S., Dr. C. G. Knott, 222
Bjurholm Aerolite, the, 110
Blackford (Dr. Charles Minor), a Curious Salamander, 389
Blake (Dr. E. M.), Ruled Surfaces Generated by Plane Movements, whose Centrodes are Congruent Conics Tangent at Homologous Points, 359
Blake (H. W., F.R.S.), Death of, 229

BRITISH ASSOCIATION : Dover Meeting of the, 463, 521 ; W. H. Pendlebury, 180, 370, 420, 495 ; Inaugural Address by Prof. Sir Michael Foster, K.C.B., Sec. R. S., President of the Association, 464 ; Evening Address "La Vibration Nerveuse," Prof. Charles Richet, 625
*Section A* (*Mathematics and Physics*).—Opening Address by Prof. J. H. Poynting, F.R.S., President of the Section, 470 ; Dr. Francis Galton on "The Median Estimate," 584 ; Prof. Forsyth on a System of Invariants for Parallel Configurations in Space, 584 ; Prof. Everett on the Notation of the Calculus of Differences, 584 ; Prof. A. C. Dixon on the Partial Differential Equation of the Second Order, 584 ; Dr. Irving Stringham on the Fundamental Differential Equations of Geometry, 584 ; Report on the Problem of Three Bodies, Mr. E. T. Whittaker, 585 ; on the Spectroscopic Examination of Contrast Phenomena,

Mr. G. J. Burch, Sir George Stokes, Principal Glazebrook, 585; Preliminary Results of a Research on the Variation of the Specific Heat of Water with Temperature, Prof. Callendar, 585; on a Flaw in Nernst's Theory of Electrolytic Solution Pressure, Dr. R. A. Lehfeldt, 585; on the Stability of an Ether containing long, thin, empty Vortex Filaments, Prof. Fitzgerald, 585; on the Absence of Hydrogen and Helium from the Earth's Atmosphere, Prof. Bryan, 585; the Thermo-Electric Properties of an Alloy containing Iron 68·8 per cent., Nickel 25·0, Manganese 5·0, and carbon 1·2, Prof. W. F. Barrett, 586; Report of the Committee on the Heat of Combination of Metals in the Formation of Alloys, Prof. Vernon Harcourt's Criticism, 586; Preliminary Report of the Committee on Radiation from a Source of Light in a Magnetic Field, 586; on the Production in Rarefied Gases of Luminous Rings in Rotation about Lines of Magnetic Force, Mr. C. E. S. Phillips, 586; Note on Deep Sea Waves, Mr. V. Cornish, 586; on the Existence of Masses smaller than the Atoms, Prof. J. J. Thomson, M. Broca, Prof. Rücker, 586; Sir Norman Lockyer, Prof. Oliver Lodge, 587; Preliminary Results of a Year's Work with the Seismograph at Mauritius, Mr. T. F. Claxton, 587; on the Progress Achieved during the Past Year at Blue Hill, Massachusetts, in the Exploration of the Air with Kites, Mr. A. L. Rotch, 587; the Hydro-Aërograph, F. Napier Denison, 587; a Portable Gravity Balance, Profs. Threlfall and Pollock, 587; Discussion on Platinum Thermometry, Prof. Callendar, Dr. J. A Harker, Dr. Chappuis, Mr. E. H. Griffiths, Prof. Carey Foster, Prof. Burstall, Principal Glazebrook, Dr. Chree, Prof. Threlfall, Mr. W. N. Shaw, 587; on the Spectral Sensitiveness of Mercury Vapour in an Atmosphere of Hydrogen, Dr. E. P. Lewis, 587

*Section B* (*Chemistry*)—Opening Address by Dr. Horace T. Brown, F.R.S., President of the Section: Fixation of Carbon by Plants, 474; a Correction, 544; the Excretory Products of Plants, Prof. Hanriot, 608; Chemical Processes involved in the Saccharification of Starch by Malt-diastase, Dr. A. Fernbach, 608; on the Combined Action o Diastase and Yeast on Starch Granules, Dr. G. H. Morris, 608; the Action of Acids on Starch, Dr. G. H. Morris, 608; Symbiotic Fermentation, Prof. Marshall Ward, Sir Henry Roscoe, Prof. Armstrong, M. Van Laar, 609; Industrial Symbiotic Fermentations, Dr. Calmette, 609; Remarkable Result observed on the Exposure of Metallic Silver to Light, Colonel Waterhouse, 609; Proposal to Establish an International Committee on Atomic Weights, Prof. Tilden, 609; on Laws of Substitution, especially in Benzenoid Compounds, Prof. Armstrong, 609; Researches on Oxidation in Presence of Iron, Mr. Fenton, 609; Experiments on the Action of Hydrogen Peroxide on Carbohydrates in presence of Iron Salts, Messrs. Morrell and Crofts, 609; on the Influence of Solvents on the Optical Activity of Organic Compounds, W. J. Pope, 609; on the Action of Caustic Soda on Benzaldehyde, Drs. C. A. Kohn and W. Trantom, 609: on the Chemical Effect on Agricultural Soils of the Salt-water Flood of November 29, 1897, on the East Coast, Messrs. T. S. Dymond and F. Hughes, 609.

*Section C* (*Geology*)—Opening Address by Sir Archibald Geikie, D.C.L., D.Sc., F.R.S., President of the Section, 496; Coal Exploration in Kent, R. Etheridge, Prof. W. Boyd Dawkins, 610; Investigations among the Upper Carboniferous Rocks of North Staffordshire, Mr. W. Gibson, 610; on a Recent Boring through the Chalk and Gault near Dieppe, A. L. Jukes-Browne, 610; the Origin of Flint, Prof. W. J. Sollas, 610; on Extra-morainic Drainage in Yorkshire, Prof. P. F. Kendall, 610; Homotaxy and Contemporaneity, Prof. Sollas, 610; on a Smoothed and Grooved Surface of Mount Sorrel Granite underlying Undisturbed Keuper Marl, Prof. W. W. Watts, 610; Prof. A. Renard on the Origin of Chondritic Meteorites, 610; Prof. W. Boyd Dawkins on the Geology of the Channel Tunnel, 610; Mr. F. W. Harmer on a Proposed New Classification of the Pliocene Deposits of the East of England, 610; Mrs. M. M. (Ogilvie) Gordon on Sigmoidal Curves in the Earth's Crust, 611.

*Section D* (*Zoology*)—Opening Address by Adam Sedgwick, M.A., F.R.S., President of the Section: Variation and Some Phenomena connected with Reproduction and Sex, 502; J. J. Lister on *Astrosclera willeyana*, 631; Prof. Johnson-Symington on the Morphology of the Cartilages of the Monotreme Larynx, 631; N. Bishop Harman, the Palpebral and Oculo-motor Apparatus in Fishes, 631; W. Garstang, First Report on the Periodic Investigation of the Plankton and Physical Conditions of the English Channel during 1899, 631; Dr. J. F. Gemmill on Negative Evidence regarding the Influence of Nutrition in Determining Sex, 631; Sir John Murray on Dr. Peterson's Experiments in the Cattegat, with the Marking and Measuring of Plaice in order to determine Distribution and Growth, 631; W. Garstang on the Artificial Rearing of Young Sea-fish, 631; Prof. McIntosh on the Occurrence of the Grey Gurnard (*Trigla gurnardus*, L.) and its Spawning in Inshore and Offshore Waters, 631; T. H. Taylor on the Embryolog of the Polyzoa, 631; Prof. MacBride on the Rearing of Larvæ of Echinidæ, 631

*Section E* (*Geography*)—Opening Address by Sir John Murray, K.C.B,, F.R.S., LL.D., President of the Section, 521

*Section G* (*Mechanical Science*)—Opening Address by Sir William White, K.C.B., LL.D., F.R.S., President of the Section, 527

*Section H* (*Anthropology*)—Opening Address by C. H. Read, President of the Section, 554

*Section I* (*Physiology*)—Opening Address by J. N. Langley, F.R.S., President of the Section, 557; Evening Address by Prof. Charles Richet, "La Vibration Nerveuse," 625

*Section K* (*Botany*)—Opening Address by Sir George King, K.C.I.E., LL.D., F.R.S., President of the Section: "A Sketch of the History of Indian Botany, 581, 604

Leduc (Stéphane), Rays Emitted by Electrified Point, 192; Wandering Globular Sparks, 264
Leeds Astronomical Society, 260
Lehfeldt (Dr. R. A.), Vapour Pressure of Solutions of Volatile Substances, 70; on a Flaw in Nernst's Theory of Electrolytic Solution Pressure, 585
Leidié (E.), the Purification of Iridium, 336
Lemoine (G.), Action of Magnesium on Saline Solutions, 360
Lemoine (J.), the Instantaneous Disappearance of the Kerr Phenomena, 336
Leonids, Observations of, 578
Leonids, the Coming Shower of, W. F. Denning, 592
Lepidoptera: Natural Selection in the Lepidoptera, Mark L. Sykes, 222; the Larvæ Collector's Guide and Calender, J. and W. Davis, 244; Catalogue of the Lepidoptera of Northumberland, Durham, and Newcastle-upon-Tyne, J. E. Robson, 590
*Lepidosiren Paradoxa*, External Features in Development of, J. G. Kerr, 93
Lepierre (Charles), Fluorine in Mineral Waters, 120
Lespieau (R.), Dichlor-3·4-butanoic Acid, 336
Letts (Prof.), Amount and Causes of Carbonic Anhydride of Atmosphere, 94
Level Bubble, Effect of Vibration on a, A. Mallock, 615
Lévy (Lucien), La Pratique du Maltage, 388
Lewis (Dr. E. P.), on the Spectral Sensitiveness of Mercury Vapour in an Atmosphere of Hydrogen, 587
Liardet (J. E.), Automatic Steering Register, 134
Library Cataloguing, a Manual of, J. Henry Quinn, 124
Life, the Nature and Origin of, Dr. F. J. Allen, 623
Life of a Star, the, Prof. J. Perry, F.R.S., 247; Dr. T. J. J. See, 519
Life-history of the Parasites of Malaria, Major Ronald Ross, 322
Light: Polarisation Experiment, J. Cook, 8; the Diffraction Process of Colour Photography, Prof. R. W. Wood, 199; the Wave Theory of Light, its influence on Modern Physics, the Rede Lecture, Prof. A. Cornu, 292; Curiosities of Light and Sight, Shelford Bidwell, F.R.S., 389; Preliminary Report of the Committee on Radiation from a Source of Light in a Magnetic Field, 586; Remarkable Result Observed on the Exposure of Metallic Silver to Light, Colonel Waterhouse, 609
Lightning Flashes, Dark, Lord Kelvin, F.R.S., 341; Dr. William J. S. Lockyer, 391, 570; Prof. W. Wood, 460; Shelford Bidwell, F.R.S., 591
Lightning Flashes, Remarkable, C. E. Stromeyer, 520; Prof. Henry Stroud, 520; T. W. Backhouse, 520; F. H. Glen, 520
Lightning, Ribbon and Dark, 423
Lightning, Magnetic Effects of, Dr. Folgheraiter, 300
Limerick (Right Rev. Charles Graves, Lord Bishop of), Death and Obituary Notice of, 277
Limnology: the Microscopy of Drinking Water, G. C. Whipple, 146; Examination of Water, W. P. Mason, 146; Dr. Hugh Robert Mill, the Reviewer, 174
Lines of Force, Magnetic, 412
Linnean Society, 93, 118, 190, 214
Lippmann (G.), Method of Setting a Collimator, 635

Lippmann (J.), an Absolute Measure of Time Based on Newtonian Constant of Gravitation, 400
Liquefaction of Gases, Liquid Air and the, T. O'Conor Sloane, 268
Liquid Interrupter for Induction Coils, an improved, A. A. Campbell Swinton, 226
Liquid, Perfect, the Motion of a, Prof. H. S. Heler Shaw, 446
Lister (J. J.), on *Astrosclera Willeyana*, 631
Living Organism, the, an Introduction to the Problems of Biology, Alfred Earl, 458
Living Pictures, H. V. Hopwood, 567
Livingstone's (Dr.) Tree, 425
Lloyd (L. L.), Organic Compounds Containing Silicon, 214
Local Government Board, Twenty-seventh Annual Report of the, 1897–8, Supplement, 73
Local University Colleges for London, 201
Lockyer (Sir Norman, K.C.B., F.R.S.), on the Chemical Classification of the Stars, 52; on the Distribution of the Various Chemical Groups of Stars, 617; on Some Recent Advances in Spectrum Analysis Relating to Inorganic and Organic Evolution, 103; on Spectrum Series, 368, 392; W. Sedgwick, 412; on the Existence of Matter Smaller than the Atoms, 586
Lockyer (Norman J.), a Manual of Locomotive Engineering, 193
Lockyer (Dr. William J. S.), Dark Lightning Flashes, 391, 570
Locomotive Engineering, a Manual of, William Frank Pettigrew, Norman J. Lockyer, 193
Locusts, Dr. Edington's Fungus-process for destroying, 16
Locusts, the Extermination by Fungus-inoculation of Cape, 426
Lodge (Prof. Oliver), on the Existence of Matter Smaller than the Atoms, 586
Loewy (M.), Simon Newcomb, Scientific Worthies, 1
Löffler (Prof.), Heredity and Tuberculosis, 109
Lommel (Dr. Eugen Ritter von), Death of, 277
London: Report of the London Technical Education Board, 141; Local University Colleges for London, 201; the University of London, 232, 246, 325; the Housing of the Offices of the University of London, 232

# NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

"*To the solid ground
Of Nature trusts the mind which builds for aye.*"—WORDSWORTH.

THURSDAY, MAY 4, 1899.

## *SCIENTIFIC WORTHIES.*

### XXXII.—SIMON NEWCOMB.

NEWCOMB must be considered, without contradiction, as one of the most celebrated astronomers of our time, both on account of the immensity of his work and the unity of view which marks the choice of the subjects treated by him.

All is linked together in our solar system: the study of the motion of each one of the celestial bodies forming part of it is based upon the knowledge of a great number of numerical data, and there exists no fundamental element whose influence is not repercussed on the entire theory of these bodies. To endeavour to build up the theory of our whole planetary world on an absolutely homogeneous basis of constants was an almost superhuman task.

The evaluation of each one of these data demands, indeed, that one should attentively go over most of the previous researches, and continue them by more thorough methods. All Newcomb's work, followed up with rare perseverance, has constantly tended to this ideal end: first to arrive at a more exact knowledge of the magnitudes serving as points of reference, and then to establish the theory, not only of all the planets, but also of their satellites on a system of constants as precise as modern observations permit. Wishing to realise in a complete manner this vast programme, Newcomb has recognised that the published observations do not always furnish the necessary information for obtaining with exactness all the looked-for elements. Abandoning, therefore, the domain of pure speculation, he has given himself up to researches which proclaim him possessed of a talent of observation of the highest order. By personal studies he has succeeded in filling many of the gaps which seriously impeded the progress of theory. Thus, in order to determine the masses of Neptune and Uranus and the elements of their satellites, he made a series of observations of great value, on which are partially founded the ephemerides inserted in all nautical almanacs.

I shall simply mention here in a few words some of the preparatory work preceding the construction of the magnificent edifice of which I have indicated the plan, on the happy completion of which the scientific world is to be congratulated. Throughout its execution one recognises the sign of a master-mind whose conclusions assume a definite character and remain acquired to science.

The solar parallax is one of the most essential data which intervene in all researches concerning the planetary system. Newcomb undertook to fix its value by the discussion of all the transits of Venus observed previously to 1882. In a very detailed memoir, he calls astronomers' attention to the danger to which they are exposed by giving an exaggerated confidence to certain modern methods. The systematic exclusion of the ancient observations cannot sufficiently be justified by discordances which exist between their results and those obtained more recently. By a minute and impartial discussion of all existing documents, Newcomb arrived at a value almost identical with the one adopted in 1896 by the International Conference of Paris.

Again, in order to obtain by an altogether independent means the value of this same constant, Newcomb undertook a determination of the velocity of light, based on the ingenious method suggested by Léon Foucault. These researches of a physical nature opened the way to an important advance in our knowledge of the heavens. In fact, we had all reason to hope that the value obtained for the velocity of light, combined with the constant of aberration, would allow us to determine the solar parallax more accurately than by the usual astronomical methods. Newcomb holds that multiplicity of methods is an essential condition of success; this motive led him to choose Foucault's method, which he applied with rare sagacity. The agreement between the different results obtained in this way by Cornu, Michelson and Newcomb is an admirable one, and testifies to the knowledge and skill of the experimenters. With the help of the values found for the velocity of light, it would have been possible to deduce the parallax, if recent observations had not revealed the uncertainty which still hovers over the real value of the aberration constants.

I cannot close the list of these preparatory studies without referring to a subject which interests the highest problems of astronomy of precision.

The observations of the planets and of the moon depend on the coordinates of the fundamental stars, of which unfortunately we possess as yet no catalogue absolutely free from systematic errors. One of Newcomb's constant preoccupations was to try to constitute a uniform system of points of reference, at least in right ascension, this coordinate having we ghty importance in the case of observations of moving bodies. The catalogues drawn up by him, and by Auwers, for the fundamental and bright stars of the ecliptic, have shared in equal measure up to a very recent date the favour of astronomers. But the use, in the same scientific research, of elements derived from different sources, presents inconveniences acknowledged for a long time. A reform in this direction had become very desirable. This circumstance has again afforded Newcomb the opportunity of manifesting the inexhaustible resources of his activity and talent. An international conference, held in Paris in 1896, under the auspices of the Bureau des Longitudes, had as its object to elaborate a common system of constants and fundamental stars to be employed in the astronomical ephemerides. Newcomb took one of the most important parts in the discussions and resolutions of this conference. At its suggestion he has undertaken, not only the research of the definitive values to adopt for the lunar-solar precession and the planetary precession, but also the construction of a new catalogue of fundamental stars in accordance with the system of elements chosen by the Paris meeting of astronomers. Newcomb has consecrated these two later years to the accomplishing of this arduous task. The catalogue of fundamental stars, which he has just finished, will come into use in the beginning of 1901, and will realise in the work of astronomers that unity and simplification so long desired.

I now come to the labours which have absorbed the greatest part of Newcomb's scientific activity: they refer to the domain of celestial mechanics.

At the time when the great work of Le Verrier had only reached the tables of Jupiter, Newcomb published an excellent theory of the two planets furthest from us, Uranus and Neptune. These tables, from the moment of their appearance, have been used by astronomers of every country.

Among the greatest triumphs of Newcomb's career must be counted his many and fruitful researches on the motion of the moon The theory of the moon bristles with difficulties. No one has yet succeeded in establishing a complete harmony between theory and observation. In his lunar tables, Hansen, in order to obtain this accordance for a limited interval of time, was obliged to attribute to an inequality arising from the action of Venus an empirical coefficient of an excessive amount, and to adopt besides an acceleration of the secular movement twice as great as that which results from the law of universal gravitation according to the calculations of two illustrious geometricians, Adams and Delaunay. Should we, as a great number of *savants* think, attribute to Hansen's number, so far from the theoretical value, an indisputable reality, and try to discover the physical causes of the anomaly; or should we see the origin of the disagreement in an erroneous interpretation of historical documents? Newcomb did not recoil before the difficulties which the solution of this problem entailed. He discussed all the occultations observed since the invention of the telescope up to a recent time; he himself examined forgotten observations, buried for one hundred and fifty years in the registers of the Paris Observatory. These neglected documents have thrown a vivid light on the question. In thus utilising an abundant harvest of new information, and correcting Hansen's theory by the exclusion of every empirical coefficient, Newcomb arrived at results of fundamental importance. He proved, agreeing in this with Tisserand's researches, that the eclipses of the Almagest, and those of the Arabs, as well as the ancient occultations, agree very well with the theoretical value of the secular acceleration; and further, as a corollary, that the most ancient solar eclipses, the representation of which would seem to demand an increase of the secular acceleration, can without scruple be left out of consideration, either because the reality of the phenomenon remains doubtful, or because there exists too great an uncertainty in the hour and place of observation.

One might without inconvenience, therefore, adopt the theoretical acceleration of 6″, correcting the mean motion and the longitude of the epoch. But whatever value is chosen, and this was not anticipated, one must, after having suppressed Hansen's erroneous inequality, resign oneself to introduce another notable empiric term of a period of about two hundred and seventy years, and of an unexplained origin; one simply notes that this amplitude is nearly that of an inequality due to Venus, the existence of which is not doubtful.

Besides this empiric inequality, Newcomb has discovered another, less pronounced, with a coefficient superior to 1″, with an amplitude of about twenty-seven days, and appearing to be associated with a long period perturbation of the excentricity and perigee. These delicate deductions have since been confirmed by the theoretical researches of Messrs. Neison and Hill, which show that the terms in question are due to the action of Jupiter. By all these investigations, Newcomb has elucidated, in a masterly way, the actual state of the theory of the motion of our satellite.

The two theories of the moon which must be considered the best are those of the two celebrated geometricians, Delaunay and Hansen; they are founded on totally different methods. By the help of a long, minute and tedious transformation, because it is a question of formulæ occupying several quarto volumes, Newcomb has rendered their expressions immediately comparable, bringing them moreover to a system of precise and uniform constants.

Further, by this comparison, he has shown that, in spite of the difference of method, the two theories lead to identical results for solar perturbations, which form the essential part of them and are indeed the only ones which were calculated by Delaunay.

I must now pass very briefly to some of Newcomb's other memoirs. One of his most original researches is relative to Hyperion, Saturn's seventh satellite, discovered almost simultaneously by Bond and Lassell.

The movement observed was in disaccord with the prediction of theory. In fact the major axis of Hyperion's orbit, instead of moving, directly, round Saturn in a century, accomplished a revolution in the opposite direction in the short period of eighteen years.

Newcomb has proved that this rapid retrograde revolution is caused by the perturbing action of the next satellite Titan.

In the various volumes of "The Astronomical Papers for the use of the American Nautical Almanac," Newcomb has published a great number of memoirs. One can follow step by step the immense progress achieved in the execution of the vast project which he had taken upon himself to accomplish.

It is difficult to convey an idea of the considerable efforts, the sagacity which must be displayed, the numerous investigations which must be accomplished, in order to make known to a sufficient degree of approximation the motion during a century of a body of our planetary system. Only those scientific men who have given themselves up to analogous studies can appreciate the enormous expenditure of physical and intellectual energy which must have been necessary to Newcomb in order to bring to a happy end the researches on the four planets nearest the sun. Newcomb has based his work on more than 60,000 observations, which he has compared with Le Verrier's tables; the perturbations have been calculated with great precision. While Newcomb has thus founded theories of these planets on a more precise basis, his celebrated collaborator, Mr. Hill, has obtained the same results for the two planets Jupiter and Saturn.

Henceforth, science will profit by the fruits of this immense labour, consisting of the tables of the planets Mercury, Venus, Mars and the Earth. In a special volume there are to be found various researches on the fundamental constants of astronomy.

We have only been able to give a short sketch of Newcomb's achievements; he is gifted with a prodigious power of work, which is testified by the extraordinarily long list of his researches.

The reception which has been accorded to them by all competent men points to their author as one of the most illustrious representatives of celestial mechanics.

This activity has embraced the most diverse branches of astronomy. Not only has he given a great scope to the intellectual movement of his country, but he has also contributed in a very successful manner to elevate the level of the civilisation of our age, enriching the domain of science with beautiful and durable conquests.

LOEWY.

## *THE TEMPERATURE-ENTROPY DIAGRAM.*

*The Entropy Diagram and its Applications.* By J. Boulvin, Professor at the University of Gand, Belgium. Translated by Bryan Donkin. Pp. xii + 70. (London: E. and F. N. Spon, Ltd., 1898.)

RANKINE'S "Thermodynamic Function $\phi$" (defined by $t.d\phi = dH$) is now called "Entropy $\phi$." The state of a pound of stuff which has only fluid stress and strain is completely defined when we know the values of any two of $p$, $v$, $t$, E or $\phi$ [during change of state the two must not be merely $p$ and $t$] where E is the intrinsic energy and $\phi$ is the entropy. When we say that E returns to its old value if we bring the stuff to the same state again, we state the first law of thermodynamics in its most general form. When we say that $\phi$ returns to its old value, we state the second law of thermodynamics in its most general form.

A curve connecting the values of any two of the above coordinates will, therefore, completely define the changing state of a pound of stuff. Rankine does not seem to have used the $t,\phi$ coordinates graphically, but he used them very much indeed in the algebraic form; and the idea that a $t,\phi$ diagram might be constructed was published by several mathematicians more than a quarter of a century ago. In truth, the idea was familiar to all students of Rankine, but until Mr. Macfarlane Gray began his crusade in favour of the use of the $t,\phi$ diagram in practical steam engine calculation, no other person had any idea of the changes that its use would effect.

When a pound of water-stuff alters in pressure and volume in any assigned way, at what rate does it receive or give out heat? This is the problem that we used to solve in the most laborious way; and so troublesome was it that I question if anybody, not a lecturer, ever worked out more than one example completely. The problem was never put before any but the most advanced students.

Now, thanks to Macfarlane Gray, this sort of problem is not only taken up and solved by the average student in the most elementary classes, but it is of all problems the one whose solution is most easily understood; and it is through such work that we now most easily introduce the average student to the laws of thermodynamics and the properties of steam and water. For twelve years it has been one of the commonest of class problems to take an indicator (or $p,v$) diagram, and assuming a certain wetness of the steam at the beginning of the expansion, to convert it into a $t\phi$ diagram.

Prof. Boulvin has not added to our knowledge of theory or the practical application of the $t\phi$ diagram, but in his well-known "Cours de Mécanique appliquée aux Machines," in 1893, he made the method known to continental students, and exhibited the conversion of $pv$ to $t\phi$ coordinates in a fourfold diagram; whereas in England such a conversion has always been on one diagram. Our method has possibly been such that the result is confusing to all but the man who carries it out; but this is the fault of all graphical methods of working problems. It has the merit of utilising the whole of a sheet of paper instead of one quarter of a sheet. The English method may be recommended to a student who wants an accurate answer. Prof. Boulvin's method may be recommended to a lecturer who wishes merely to *illustrate* the connection between the $p,v$ and the $t\phi$ diagrams.

The solution of the problem is really very misleading, for, invariably, the assumption is made that there is no moisture in the cylinder at the end of the exhaust. This assumption is the basis of the method used by Hirn and his numerous followers in that kind of study of the steam engine which is usually supposed to be complete. It does not seem to be understood that if there is any moisture in the cylinder at the end of the exhaust, Hirn's

elaborate analysis is utterly wrong; and yet there is every ground for believing that even when steam is somewhat superheated when leaving the boiler, even well-jacketed cylinders are never free from moisture. I am sorry to say that the Hirn analysis is often employed for cylinders with no jackets when the steam supplied is known to be quite moist. As an academic exercise, no one would object to the method of study if students were informed of its uselessness in most practical cases, but, unfortunately, this information is never given in treatises which advocate the method.

If there is no leakage past the piston, we are sure that, from the beginning of the expansion to the release, we are dealing with the volume and pressure of a quantity of stuff which does not alter in amount. This is only a portion of an indicator diagram; and, as I have already pointed out, our usual study of it is based upon an unwarrantable assumption. But what are we to say of men like Prof. Boulvin, who pile upon this Pelion, Ossas of further assumption for the sake of making pretty academic problems, and then publish the solutions of these problems as if they were of practical importance?

Of course we may, if we please, say that when steam is released to the condenser, we can imagine the whole change as occurring in the cylinder itself; only we ought to remember that we are substituting a very simple hypothetical process for a very complicated reality, which has almost nothing in common with it. We ought to remember that the very pretty, beautifully complete, cyclic $t\phi$ diagrams, which we obtain from childish assumptions, may get to be looked upon by students, and even by ourselves, as having a real meaning.

The engineering teacher is much too apt to fill up the time of students with an elaborate and systematic course of instruction on a subject in which only a few lessons are essential, and, indeed, in which only a few lessons ought to be admissible. In some German schools we have systematic courses on graphical statics lasting whole terms or years. Courses on practical geometry are never supposed to be of use unless the student draws every imaginable kind of curve, draws every imaginable kind of intersection of surfaces. When some man who really thinks for himself has, after endless opposition and worry, convinced teachers that a certain kind of exercise is of value, his converts make his modest proposals into an elaborate academic system. There is no imaginable problem which does not become part of an elaborate course of exercise work. A student becomes wonderfully learned, but he loses the power to think things out for himself. Macfarlane Gray's method of study may be made part of a student's mental machinery in a few lessons, and in these few lessons it enables an elementary student to do easily what Hirn did with so much trouble; but, in truth, its great value lies rather in its enabling students to work out for themselves the well-known results of Rankine and Clausius. They see at a glance that liquefaction accompanies adiabatic expansion. They very quickly find the $p,v$ law of adiabatic expansion of steam of any wetness. They can calculate easily the work that would be done by a perfect steam engine using the Rankine cycle, and many other important things which the average student used to take on trust. Not only does the $t\phi$ diagram enable one to see at a glance the reasonableness of much that used to be very obscure, but it clears the ideas of men who still prefer to work algebraically.

It is quite usual now in classes for students to prepare for themselves $t\phi$ sheets on which not only are the $t\phi$ lines for a pound of water and a pound of steam laid down, but also lines of constant $p$ and constant $v$ and constant E for wet, and also for superheated steam; and with these sheets many interesting problems may be worked.

The $t\phi$ sheets for a perfect gas, with lines of constant $p$, $v$ and E, are even more valuable than such sheets for steam when one desires to convert an indicator diagram of a gas or oil engine into a $t\phi$ diagram. But, indeed, the $t\phi$ diagram is nothing like so valuable in gas engine work as in steam engine work, for rate of heat reception is quite easily obtainable from the $p,v$ curve of a perfect gas. When we also remember that all idea of time is absent from a $t\phi$ curve, it will be seen that practical gas engine people are not likely to make much use of it.

Prof. Boulvin introduces his subject by a chapter on the laws of thermodynamics. He begins with—"The study of the changes produced in bodies by heat is based upon certain *fundamental laws* as the laws of Mariotte (or Boyle) and of Gay-Lussac (or Charles)." He defines absolute temperature as what is shown by an air thermometer, the zero of which is 273° C. below the ordinary zero. If adequate explanation were given, there might be no objection to these and other statements; but I am inclined to think that the ordinary reader will find such an introduction misleading. I think that some difficulty would be cleared up if the author proved the truth of the fundamental equations for perfect gases, instead of merely assuming their truth; it would lead to a much simpler treatment of the next two chapters. Parenthetically, I would observe that he is quite mistaken in thinking that a *small* error in measuring clearance in a gas engine cylinder will lead to very wrong values of $k$ in the expansion curve, $pv^k$ constant.

It would be interesting to know what the author means when, after speaking of Regnault's value 0·48 for the specific heat of steam, he says, "and this is about the same value as it would have if treated as a permanent gas, and its density calculated from its molecular weight." I think that there is almost no point of view from which this statement must not be regarded as absurd.

On the whole, the author may be said to have given an account of the subject which it is worth while for a beginner to study, should he not be able to lay his hands on the several better accounts which have already been published in England. It is a pity that the translator did not think it worth while to alter Prof. Boulvin's illustrations, for these have compelled him to use letters which will give trouble to the English student. Rankine's letter $\phi$ is universally used in England and America for entropy; here we have S used instead. I am wrong in assuming that the use of the foreign illustrations compelled the translator to employ these letters; for I see that he follows Prof. Boulvin in using $r$ for latent heat, $\lambda$ for Regnault's total heat; and, of course, he uses A for Joule's equivalent. In a book intended for English engineers, I think that either C.G.S. units or English engineers' units ought to be used. In this translation we find the hybrid units of French engineers.

Many of the names mentioned in connection with the history of thermodynamics are quite unknown to me; I nowhere find any mention of the names of Lord Kelvin or of his brother the late Prof. James Thomson, who first demonstrated the connection between pressure, temperature and change of specific volume on change of state. Rankine's name is not mentioned either, although to the English engineer this seems like leaving out the name of Columbus in a history of the discovery of America.

In the section referring to "diagrams of $CO_2$ marking the critical point," of course the name of Dr. Andrews is not mentioned, but those of Regnault and Zeuner, Cailletet and Mathias are. Of course, A is used instead of J for Joule's equivalent throughout this book.

The translator says that Prof. Unwin has read over the proofs. I wonder whether he looked over the translator's preface, in which he states, among other curious things, that "entropy in its strict sense has no meaning if employed to represent the changes of state of a fluid flowing through a vessel, and more or less throttled in its passage." If he means that a foolish man may make mistakes in using a $t\phi$ diagram, he is right enough. But if he means that a certain quantity of stuff in a certain state has not just as definite a quantity of entropy as it has of pressure or temperature, he makes a mistake which is by no means an unusual one.

Perhaps, on the whole, it is well not to extend to the translator much of the credit which one may give to the author of the book. The author may never have heard of Rankine or the Thomsons or Andrews or Maxwell, but it is really unpardonable that in the translator's list of the works dealing with "the subject of entropy" there should be no reference to anything written by Rankine.

JOHN PERRY.

## UNSCIENTIFIC NOTES.

*Haunts and Hobbies of an Indian Official.* By Mark Thornhill, author of "Adventures of a Magistrate in the Indian Mutiny." Pp. xii + 346. (London: John Murray, 1899.)

THIS is a collection of notes on various subjects jotted down by an Indian civilian, who, during part of his Indian career, kept a diary which was, he says,

"chiefly devoted to observations on the birds, insects and animals whose acquaintance I made in my garden, or which I beheld on the bed of the river beyond."

Like many writers in the earlier half of the passing century, Mr. Thornhill uses the word animals in the restricted meaning of mammals. Occasional notes on the weather, on some of the natives of India, and on their habits, institutions and superstitions, and an account of a tour in the Deyra Dun at the base of the Himalaya, are added, and make a thoroughly readable and even an interesting book, though not one to which those desirous of information as to the "birds, insects and animals" of Northern India can be recommended to turn. The best portions of the work are those descriptive of the people of India and of the scenery; the changes of the seasons, and their effects, especially on insect-life, are also well described, but similar accounts have been given by other writers. The observations recorded were evidently made in parts of the North-western Provinces of India.

It is chiefly as a contribution to the zoology of Northern India that Mr. Thornhill's book demands notice here; and in this respect it would be difficult to find a more unscientific work. For science is essentially the accumulated experience of many men, and they who trust entirely to their own observations and neglect to make themselves acquainted with facts recorded by others, must not be surprised if the majority of their accounts are superfluous, and some of them erroneous. In the present work we have description after description of certain habits of the animal world well known to every Anglo-Indian, and useless to those unacquainted with India, because the author is unable to identify the animals observed. For instance, on p. 192 he describes in considerable detail a remarkable bird's nest. But although he must have devoted time and labour to obtaining and describing the nest, it does not appear to have occurred to him to inquire what bird built it, or whether any other observer had investigated this interesting form of bird-architecture. Yet from the description of the nest, and from the manner in which the structure was suspended from high grass, it is easy to recognise the nest of a weaver bird, and even to identify the species as probably the striated weaver bird *Ploceus manyar.* Any one who compares Mr. Thornhill's notes with those in Jerdon's "Birds of India," or better still with the elaborate account given in Hume's "Nests and Eggs of Indian Birds," must appreciate how useless the first-named are.

In the case just quoted, Mr. Thornhill, though his observations add nothing to what was well known before, does not mislead; so another instance may be taken, when his information is not only imperfect but incorrect. The following are extracts from his account (p. 118) of the animal well known in India under the name of the "musk-rat."

"This rat, fortunately, does not make its residence in the houses, and indeed it only occasionally enters them, and then as a rule by night. I do not know whether after all it is a true rat. In appearance it more resembles a very small, nearly hairless, ferret. It is of a drab colour, and has that half-transparent look noticeable in young mice and unfledged chickens. Its presence is manifested by a squeaking cry, accompanied by an intolerably sickly odour, something resembling musk. The odour is so penetrating that, according to the European popular belief, it will pass through the glass of a bottle and flavour the liquor within. The fact is correct, but not the explanation. Beer and wine are certainly occasionally flavoured by these rats running among the bottles that contain them, but the odour penetrates not through the bottle, but through the cork."

The so-called musk-rat of India is, of course, a large shrew, and resembles a ferret about as much or as little as the common English shrew does. It varies in colour, but is generally slatey-grey to bluish-grey. If it does not spend the day actually in houses, it haunts their immediate neighbourhood, merely hiding in holes. Its presence is not necessarily manifested by any odour, as Sterndale has shown. Lastly, the absurd old story that liquors in bottles become impregnated with the peculiar odour of the secretion from the lateral glands of the musk shrew, whether the scent was supposed to pass

through the bottle or through the cork (the corks, it should be remembered, were almost always covered with resin outside), was disposed of, as most of us believed for ever, by Jerdon thirty-two years ago, when he pointed out that liquors bottled in England were never impregnated. This view has been confirmed by later observers, amongst others by McMaster and Sterndale. When Indian-bottled beer or wine was tainted, the mischief was doubtless due to the use of dirty bottles or contaminated corks.

But even on subjects apart from zoology, Mr. Thornhill's information cannot always be trusted. Thus, on p. 213, he discusses the signification of the names Siwalik (or as he writes the word Shewalic) and Himalaya. Incidentally (p. 212) he states that the Siwaliks are of a different geological formation from the Himalayas, which is correct, and that they are considered to be of far greater antiquity, which is the reverse of the fact. Then he proceeds to remark that the name Siwalik is properly the designation of the entire Himalaya west of the Ganges, and as such is used invariably by the native historians; he quotes the story from one of the latter, that the term is derived from two Hindi words *sewa* and *lac* (thrice misprinted *lae*), meaning one and a quarter lakhs or 125,000, and that this denotes the number of peaks, and he states that Himalaya signifies the "Necklace of Snow." On questions of this kind Yule and Burnell's Glossary or "Hobson-Jobson" is a generally admitted authority, and a reference to it shows how incorrect Mr. Thornhill's account is. The origin of the term Siwalik is doubtful, but by the earlier native historians of India the name was not applied to the Himalayas at all, but to a tract of country much further to the southward; the story about 125,000 peaks is absurd, and the name Himalaya is derived, according to Sanscrit scholars, from *hima* snow and *alaya* an abode, and not from *hima* and *mala* a necklace.

One extract more must be given. Some of the subjects above mentioned may be regarded as matters of opinion, but the last quotation to be made betrays a want of acquaintance with elementary astronomy surprising in a man of good education. No comment is necessary except that all India is in the northern hemisphere, and that in the countries referred to in the work before us the pole star is from twenty-five to about thirty degrees above the horizon. At p. 100 there is the following paragraph; the italics are, of course, not in the original.

"The constellations are not quite the same as those we see in England: *those that in England lie far to the north are here invisible*, while we look on many that in England never rise above the southern horizon."

W. T. B.

## ALPINE GARDENING.

*Die Alpen Pflanzen in der Gartenkultur der Tiefländer. Ein Leitfaden für Gärtner und Gartenfreunde.* Von Erich Wocke. Pp. xi + 257. (Berlin: Gustav Schmidt, 1898.)

THIS work is apparently written with a view to do for German gardeners and lovers of alpine flowers what Mr. William Robinson's "Alpine Flowers for English Gardens" (published in 1870, but long since out of print) has accomplished for their British *confrères*. Indeed, the author has treated his subject on somewhat similar lines. He is head gardener at the Zürich Botanic Gardens, and enjoys the great advantage of being able to study alpine plants in their natural conditions.

Nowadays every one is more or less interested in the cultivation of alpine plants, but comparatively few know how to grow them successfully, or to make suitable miniature Alps—popularly known as "Rock Gardens"—so as to resemble natural conditions at low elevations. Time was when heaps of clinkers and boulders of bricks thrown together anyhow were proudly designated as "rockeries." People know more about these things now, and those who do not, but would like to, may peruse with advantage the treatise under notice.

Mr. Wocke has dealt with the cultivation, propagation, and most suitable treatment for Alpine plants in a thoroughly practical manner, and German gardeners at least can no longer complain of the want of a good book on this subject. The reader is made acquainted with the conditions under which the various plants thrive naturally, so that he may know precisely how to treat a plant coming from a certain region or elevation. Plants that love the glare of the sun, or the shadow of a rock, or the moist, mossy bank of the mountain torrent, obviously require somewhat different cultural treatment; and the most successful gardener is he who endeavours to imitate nature as closely as possible.

The construction of the rockery is a most important matter, and the author rightly deals with it at some length. As a rule, horizontal fissures for the roots of plants should be avoided, being contrary to the natural downward direction taken by these organs. The reader may obtain a good idea of what a rockery should be like from the one in the Royal Gardens, Kew, although here, curiously enough, the natural state of things has been cleverly turned upside down, without however, producing unpleasant effects. Thus on the summit of the rocks—or miniature Alps—the tallest plants are placed, while at the base the dwarf and stunted forms luxuriate. As Mr. Wocke points out, plants have a tendency to become dwarfer and more stunted in growth the higher they ascend the mountain side.

A valuable list of the best Alpine and sub-Alpine plants is given, with indications as to their native habitats, and the conditions most suitable for them under cultivation. In addition, special lists of plants adapted for particular situations are given, so that the reader may see at a glance which kinds will thrive in, say, moist or dry, warm or cool, sunny or shady positions.

The last chapter in the book is devoted to rectifying the nomenclature of certain more or less well-known plants, but that is a matter which concerns the botanist more than the gardener.

On the whole, Mr. Wocke's book, which is illustrated by twenty-two explanatory woodcuts and four photographs of rock gardens (at Newton Abbot, by the way), is a welcome addition to the literature on Alpine gardening. With one or two trifling printer's errors in the botanical names, the work bears traces of having been carefully edited.

JOHN WEATHERS.

## OUR BOOK SHELF.

*Commercial Cuba. A Book for Business Men.* By William J. Clark. With an Introduction by E. Sherman Gould. Illustrated. Pp. xviii + 514. (London: Chapman and Hall, Ltd., 1899.)

A THOROUGHLY practical book written from the standpoint of the American trader, "Commercial Cuba" lays no claim to either literary or scientific merits. From its own point of view it would be difficult to find anything more exactly adapted to the needs of the moment. From personal experience in Cuba, Mr. Clark is able to advise his countrymen as to the necessity for adapting their ways of living and of dealing to the peculiarities of a tropical West Indian climate and a Spanish-American population of conservative habits.

In speaking of the population, the author points out that there is no danger of Cuba becoming a second Haiti, as statistics show a tendency for the negro element to increase very slowly, if not actually to die out. Practical hints as to the preservation of health in the tropics occupy one chapter, in which the hygienic virtues of coco-nut milk are strongly insisted on. Every aspect of the economic life of Cuba is touched upon in turn, and lists are given of the more important products, with hints as to those which deserve more attention than they have yet received. A detailed account of each province, with a condensed gazetteer giving information as to every town and village, conclude the work.

The report, taken as a whole, amply confirms the general belief as to the extraordinary riches of Cuba, which has continued to flourish under difficulties imposed by population and government which no less favoured land could have endured. When the oppressive laws have been repealed, the way to the waiting markets of the United States thrown open, and a flood of American capital and American enterprise directed to its ports, Cuba promises to become all that its discoverers dared to dream. Hitherto the wealth of the island has lain in the plantation products, and mainly in two crops—tobacco and sugar; but the mineral resources appear to be enormous, and are practically untouched There exists no adequate survey of the island, either topographical or geological, and the knowledge of the native flora and fauna is still very incomplete.

Mr. Clark, in discussing the labour problem, hazards the opinion that the future working population of Cuba will be largely composed of Italian immigrants, to whom the climate, prevailing religion, and mode of life in the island will prove particularly congenial, while the language will present little difficulty. All these conditions will militate against the immigration of negroes from the Southern States, while the coloured people of the overcrowded islands of the British West Indies are considered by the author to be too poor in physique to be desirable in Cuba.

*The Free Expansion of Gases: Memoirs by Gay-Lussac, Joule, and Joule and Thomson.* Translated and edited by J. S. Ames, Ph.D., Professor of Physics in Johns Hopkins University. Pp. 106. (New York and London: Harper and Brothers, 1898.)

THIS forms the first of a series of handy small volumes containing reprints and translations of classical papers, relating to various branches of physics, which are to be issued under the title of "Harper's Scientific Memoirs." Messrs. Harper are to be congratulated on their enterprise in launching a venture which should at least prove of great service to students, especially to students of the comparatively advanced type. They are also to be congratulated on having secured so well qualified a general editor as Prof. Ames, who is personally responsible for the contents of this first volume. That such a series should be issued at all is a remarkable evidence of the development of physical study and research in America, for it presupposes a considerable public to whom such papers are matters of sufficient interest to induce a purchase. Each paper is accompanied by a few lines of biography, and is printed in a practically complete form, with the omission only of tabular or illustrative matter which could be spared without serious loss. A few notes, giving corrections or explanations, are added, and the volume is completed by a list of books and articles of reference. In a short preface Prof. Ames draws attention to Gay-Lussac's experiments—the account of which forms the first paper in the volume—as affording a justification of Robert Mayer's assumption that the heat developed in compressing a gas is the equivalent of the work spent, the assumption, namely, on which Mayer's estimate of the mechanical equivalent of heat was founded. But it does not appear that Gay-Lussac's work, even if Mayer was acquainted with it, supplied the *lacuna* in his reasoning, or in any way detracted from the credit due to Joule for his later settlement of the matter.

The bibliography might with advantage have included a reference to the remarkable application, which in recent years has been made by Linde, of the slight cooling effect which a gas suffers in free expansion. The small cooling effect which was discovered by Thomson and Joule, the investigation of which is described in the papers reprinted here, has sufficed in Linde's hands to enable temperatures to be reached which are only a little short of the absolute zero. Incidentally, the work of Linde and Dewar has shown that the effect in hydrogen is a cooling effect, as it is in other gases, and it is to this that the liquefaction of hydrogen by Dewar is due.

J. A. E.

*The New Science and Art of Arithmetic for the Use of Schools.* By A Sonnenschein and H. A. Nesbitt, M.A. Pp. x + 501. (London: Swan Sonnenschein and Co., Ltd., 1899.)

*A School Arithmetic.* By R. F. Macdonald. Pp. viii + 264. (London: Macmillan and Co., Ltd., 1899.)

MESSRS. Sonnenschein and Nesbitt's volume is a modification of one which appeared in 1870, and has for some years occupied a foremost place among school arithmetics. A number of text-books, in which the principles as well as the practice of arithmetic are treated, are now available; but the changes made by Messrs. Sonnenschein and Nesbitt should enable their work to hold its own among them. Several chapters have been remodelled in order to render the demonstrations easier; a new chapter on the properties of fractions has been introduced; least common multiple is now connected with the Euclid, Book V., and various other additions and alterations have been made to bring the volume up to date in the methods of work described.

A knowledge of the theory of arithmetical operations is essential to the student of mathematics; but ability to accurately work examples is more valuable in ordinary life than a comprehension of the principles involved in the processes employed. The only way to acquire facility in solving problems, or quickness and accuracy in arithmetic, is by steady practice; and abundant material for exercise with these objects in view is provided in Mr. Macdonald's volume. Sufficient information as to methods of working is given to enable the pupils to understand how to apply the various rules, but no attempt has been made to explain the reasons of the processes described, the purpose of the author being to establish and extend the knowledge of pupils who have already had a training in the principles of arithmetic. The volume practically consists of exercises, most of which are in problem form, and many are of the kind met with in everyday life. For students in Schools of Science, and pupils whose arithmetical faculties have become rusty, the book should be found especially suitable.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### The Chief of the American Nautical Almanac.

PAGE 542 of the issue of NATURE for April 6 contains an announcement that Dr. T. J. J. See has been nominated as Chief of the American Nautical Almanac Office; but as this is entirely erroneous, I venture to hope you will correct it. Prof. See has been assigned to a subordinate position in the Naval Observatory, and has nothing whatever to do with the Nautical Almanac Office. WM. HARKNESS.

Nautical Almanac Office,
U.S. Naval Observatory, Washington, April 18.

[The announcement referred to by Prof. Harkness was based upon information given in *Science*, and was corrected in the following number (p. 562) upon the authority of the same journal. —ED.].

### Wehnelt Interrupter.

IN a previous communication to this journal (p. 438), I pointed out various methods of controlling the Wehnelt interrupter with a view to preventing the destruction of Crookes' tubes. Since then I have made a series of observations which confirm what was previously stated. The principle upon which the experiments were conducted was to keep all the factors constant with one exception, the amperage, voltage, results upon the fluorescent screen and photographic plate being carefully noted and registered by means of an X-ray meter. In one set of experiments the voltage was varied, in another the density of the solution, in the third the size of the platinum, in the fourth the self-induction of the primary coil. By varying any of these, or by a combination specially suited for different purposes, complete control of the Wehnelt was obtained in the way of greater or less fluorescence, actinic power, and steadiness of the screen. Briefly stated, it was found that all these effects decreased as we lowered the voltage, the self-induction of the primary, the density of the electrolyte, and the size of the platinum.

Early in these investigations, great differences between the readings across the Wehnelt and those across the terminals of the primary were observed, for the most part indicating increase in the former. An extended series of observations was made by means of Lord Kelvin's electrostatic voltmeters and ampere gauge, and a relationship between all the different factors was clearly demonstrated. Different induction coils were used, in one of which the self induction could be altered by withdrawing the soft iron core. Briefly put, it may be said: (*a*) that there was a corresponding decrease in the readings across the Wehnelt as the voltage in the primary decreased; (*b*) different conditions, such as length of spark gap, or different vacuum in the Crookes' tube placed in the secondary circuit, affected the readings considerably; (*c*) the increased voltage across the Wehnelt seemed to depend upon the amount of self-induction in the primary. In this group of experiments, it was noted that, as the self-induction increased, the voltage increased, the amperage decreased, and the number of interruptions also decreased. A non-inductive resistance was made with a view of confirming the results, and it was used instead of the primary of the ordinary coil. In this there was, however, sufficient self-induction to work the Wehnelt under certain conditions. With this arrangement, not a single reading across the Wehnelt was higher than that of the voltage across the primary. J. MACINTYRE.

Glasgow, April 28.

### Polarisation Experiment.

BY the following simple arrangement a single pile of glass plates may serve at once as polariser and analyser, and be used to study or to exhibit on a screen the interference colours with mica or crystal sections. It may not be new, but I have not seen it given anywhere. A beam of light is reflected down from a pile, polarised in the plane of reflection. Passing through a double-refracting crystal, it is resolved and then reflected by a common mirror under the crystal. On passing through the pile, which polarises by refraction in a plane at right angles to the plane of first polarisation, it shows the interference colours. Using sunlight and interposing a convex lens, we may by this simple means project the interference rings of crystal sections.

Central College, Bangalore, India. J. COOK.

### Gecko Cannibalism.

A FEW days ago, on opening the stomach of a young female gecko (*Gecko monarchus*, a species which occurs fairly commonly in the compound outside our bungalow here), it was found to contain, in addition to a caterpillar and some other remains which I could not identify, a smaller gecko of the same species; this, judging from its position in the stomach, had evidently been eaten head foremost, and was quite entire.

The lengths of the two individuals were:

| | |
|---|---|
| Larger individual | Tip of snout to cloaca, 57 mm. (tail broken off). |
| Smaller ditto ... | Tip of snout to cloaca, 32 mm.<br>Tip of snout to tip of tail, 74 mm. |

Günther, in his "Reptiles of British India," alludes to geckos as being known to destroy "the younger and weaker members of their own species," and he describes the individuals of *Gecko monarchus* as "pugnacious among themselves": but the fact that an animal will prey upon another of its own species while living under completely natural conditions and with an abundant supply of its normal insect food seems worth recording. F. P. BEDFORD.

Singapore, March 23.

### "Asia, the Land of Rice."

THROUGH the medium of your pages I would ask, Can any of the numerous readers of NATURE give information as to how or from what origin the name Asia came to be applied to a large portion of the earth's surface? Did it in olden times belong more especially to that district which we now term India? Was the name Asia used by any race of people to denote the land of spices and other valuables, whose products were brought by caravan across Persia and onward by way of the Red Sea?

In the last number of the *Journal* of the Polynesian Society (vol. vii. 185) an interesting paper, by Mr. S. Percy Smith, the Surveyor General for New Zealand, is published, "Hawa-iki: the whence of the Maori," in which he shows that Polynesian traditions tell that the Maori people of New Zealand originally started on their migrations through the isles of the Pacific from a large country which they name "Atia-te-varinga."

"In Madagascar, the name for rice is *vari* or *vare*; in Sunda (Java), Macassar, Kolo, Ende, rice is *pare*; in the Bima tongue it is *fare*; in Malay it is *padi* and *pari*. It is stated that the Arabs changed the original Malay *f* into *p*, so that originally the Malay name was *fari*."—"It is sufficiently clear from the above that *vari* means rice, and the Rarotongan tradition is correct, though not now understood by the people themselves."—"It would seem from this that Atia was a country in which the rice grew, and the name Atia-te-varinga may be translated Atia-the-be-riced, or where plenty of it grew."

In the word *varinga* the suffix *nga* is significant of the plural, and so we get "Atia the rice-growing land." TAYLOR WHITE.

Wimbledon, Hawkes Bay, N.Z., February 9.

## RECENT SCIENCE IN ITALY.

A BRIEF survey of recent numbers of the *Transactions* published by the Reale Accademia dei Lincei, or by the various other Italian Royal scientific academies, will amply show that the country to which we are indebted in the past for the telescope, the mariner's compass, the voltaic cell and other equally valuable inventions, is keeping well to the fore in all advancements of modern science.

In mathematics there have appeared, during the year 1898, papers by A. Brambilla on Steiner's surfaces, and on the surfaces of Veronese, also on the principal polygons of a gibbous quartic with a double point; while G. Gallucci has dealt with tetrahedra inscribed in a gibbous

cubic. Capelli has continued his researches on the reducibility of algebraic equations. Papers dealing with kinematical considerations have been published by E. Cavalli and C. Pietracola. The theory of groups forms the subject of papers by G. Bagnera and G. Fano; while the geometry of hyper-space and non-Euclidian geometry have received contributions from R. Banal, E. Bertini, L. Berzolari, L. Bianchi—Berzolari's paper being on an extension of Meunier's and Euler's theorems to hyper-spaces.

Of papers on higher geometry, we may note those of F. Enriques on the double planes of linear order $p^{(1)} = 1$, and on surfaces which possess a sheaf of rational curves; besides other papers by F. Amodeo, E. Ciani, B. Levi, M. Pieri, P. Pizzetti, and E. Veneroni. The Wronskian determinant has been treated by E. Bortolotti and P. Vivanti. A number of papers dealing with questions chiefly of analysis have appeared by U. Amaldi, P. Burgatti, E. Bortolotti, T. Cazzaniga, S. Pincherle, U. Scarpis, C. Severini, and others. A review of Italian mathematical work would not be complete without some reference to G. Vailati's historical papers, dealing chiefly with the early theories of mechanics.

Passing to astronomy, we find that P. Tacchini has continued his observations on the sunspots, protuberances and faculæ at the Roman College during the year. Observations have been contributed by E. Millosevich on the comet Perrine, on the planet DQ, 1898 (433), and on the last intrajovial planets. Contrary to the common opinion that the astronomy of the ancients was based exclusively on the geocentric hypothesis, Schiaparelli has shown that Heraclitus Ponticus, a disciple of Plato, had already adopted the theory that the sun was the centre of the orbits of the planets, while the earth remained the centre of the universe, and of the lunar and solar rotations—a system substantially that of Tycho.

A considerable number of additions to our knowledge of terrestrial physics have appeared during the year. Seismology has been well represented by G. Agamennone, who has occupied himself with determining the velocities of propagation of the earthquakes of Aidin and of Pergamos (Asia Minor) of 1895, and the earthquakes of India, of Labuan, and of Hayti of 1897; while P. Tacchini has considered the Emilia earthquake of 1898. Volcanic phenomena have been closely observed on Vesuvius by R. V. Matteucci. The year 1898 witnessed the rare appearance of flames on the volcano, which have been attributed by Semmola to jets of incandescent gas at a high temperature, unaccompanied by combustion; while Matteucci differs in thinking that these flames are due to the imprisonment of inflammable substances. The formation of a cupola of lava on Vesuvius forms the subject of another note by Matteucci. A highly promising field of research has been opened up in a paper, by the same writer, on the physics of flowing lava, dealing with the effect of artificial refrigeration on the crystallisation of the magma. The probable presence of coronium in the gases of the Solfatara and of Vesuvius is dealt with by F. Anderlini, R. Nasini and R. Salvadori. Bassani describes the formation of a small vent in the Solfatara.

F. Morano, in his experiments on the thermal conductivity of the rocks of the Campagna, has added fresh links of evidence on that debatable point, the age of the earth; while the second bone of contention betwixt mathematicians and geologists—the glacial period—forms the subject of a note by L. De Marchi, in reply to objections of Arrhenius.

G. Folgheraiter has recently continued his investigations on the secular variations of magnetic dip as revealed by the magnetisation of ancient vases. At the observatory of Capodimonte, the variations of the magnetic elements have been closely studied by F. Contarino and V. Tedeschi, the latter concluding that at the present rate of decrease, the magnetic declination would vanish in 113 years.

F. Angeletti has devoted his attention to the rectification of the terrestrial meridian, and has found for the earth's quadrant the value 10,000,855·76477 metres. On Mount Etna and its neighbourhood an important series of meteorological and gravitational observations have been carried out by A. Riccò. E. Oddone, working in the neighbourhood of Pavia, has investigated local variations of gravity, and the distribution and circulation of underground waters. Finally, a series of observations has been carried out on the steamer *Aspromonte* on the temperature and colour of the waters of the Adriatic and Ionian seas, of which A. Riccò and G. Saija have published a general *résumé*.

Passing from the physics of the earth to physics proper, a prominent place must be given to E. Villari's investigations on the Röntgen rays, referring more especially to their action in promoting the discharge of electrified bodies. Various experiments made by screening these rays off partially by the aid of tubes, all tend to the conclusion that the rays do not themselves promote the discharge, but cause it by means of the air on which they act. The diffusion of Röntgen rays and the influence of secondary rays emitted by bodies on which they fall have been considered at some length by R. Malagoli and C. Bonacini, whose views have been criticised by Murani. A. Battelli has continued his investigations on the nature of Röntgen rays by examining the analogy between these and kathodic rays. Other properties of Röntgen rays are dealt with by G. Guglielmo, A. Ròiti, A. Sandrucci and others. Several papers have appeared from the pen of that fertile physicist A. Righi, dealing, among other points, with the kinematic interpretation of Zeeman's phenomenon, and with the absorption of light in a magnetic field. The former of these subjects is also dealt with by O. M. Corbino. The properties of caoutchouc have been investigated by O. M. Corbino and F. Canizzaro, with regard to the variations of its dielectric constants due to traction; while M. Cantone has studied the traction and the accompanying phenomena of hysteresis from a mechanical point of view, applying his results to the determination of "Poisson's ratio." The velocity of Hertzian waves forms the subject of a paper by V. Boccara and A. Gandolfi, while Murani proves, contrary to the assertion of Le Royer and Van Berchem, that a coherer is not adapted to exhibit the maximum and minimum points of stationary Hertzian waves. In thermo-electricity, we have P. Straneo's papers on the temperature of a bimetallic conductor, and on the simultaneous determination of thermal and electric conductivities of metals. In electricity proper, we may refer to Grassi's calculation of the dimensions of induction in a continuous current dynamo, and his note on the work of magnetisation in an open cycle; A. Dina's application of aluminium to transform alternating into continuous currents: F. Lori's studies on the capacity of condensers; and A. Ròiti's paper on the two discharges obtainable from one condenser. Of thermodynamical interest are G. Bruni's series of papers on certain solid solutions, and on the equilibrium of amorphous mixtures, and of systems of two and three components with a liquid phase. C. Del Lungo deals with the density of liquids and saturated vapours considered as a function of the temperature.

In chemistry, a long series of quantitative and qualitative analyses have been conducted by Oglialoro, in conjunction with O. Forte and G. Cabella, on the waters of the baths of Belliazzi in the island of Ischia.

Menozzi, experimenting on the behaviour of certain organic nitrates in contact with the earth, has shown that hippuric acid is not absorbed or decomposed by the constituents of ordinary earth, though certain salts of this acid, similarly treated, undergo transformation. A.

Piutti has discovered a new test for the presence of wood in paper, namely chlorohydrate of *o*-Br-phenetidin, which tinges the woody fibres a bright yellow, while cellulose, ordinary fibres of cotton, wool, silk and linen are unaffected. A large number of other papers on certain new organic derivatives have been published in the *Rendiconto* of the Naples Academy, partly under the authorship of Piutti, working in conjunction with Piccoli, partly as the result of work done in Piutti's laboratory; while a detailed study of the crystallography of certain other new organic compounds, illustrated by diagrams, is contributed to the *Rendiconti* del Reale Istituto Lombardo by Boerio. Papers dealing with the methylation of the indols, and the bases derived from them, have been contributed to the *Atti dei Lincei* by A. Piccinini, G. Plancher and Bettinelli.

A geographical congress was held last April, in connection with the centenary celebrations of Paolo Toscanelli and Amerigo Vespucci.

In geology, mineralogy, and palæontology, a number of papers have appeared, but these are chiefly of local interest. We may, however, mention G. Gemmellaro's description of a new genus of brachiopods from the Sicilian *Fusulina* limestone; Artini's account of a meteorite which fell in the Somali peninsula; Bassani's work on the ichthyofauna of the eocene limestones of Gassino in Piedmont; and Taramelli's exposition of Schardt's theory, according to which a large extension of the Swiss pre-Alpine rocks is to be regarded as a limb of the secondary formation which at one time covered the Alps much further to the south.

Botany is represented by Delpino's description of several new instances of myrmecophilous plants furnished with extra-nuptial glands; A. de Gaspari's contribution to the biology of ferns dealing with spore dissemination, acarophily and myrmecophily; L. Buscalioni's work on the origin of vascular elements in the growing point of monocotyledonous roots, and his joint paper with R. Pirotta on plurinucleate vascular elements in Dioscoreaceæ; and B. Longo's researches on chromatolysis in vegetable nuclei, and on the affinities between the Rosaceæ and Calycanthaceæ.

A prominent place in the zoological literature furnished by Italy must be accorded to B. Grassi's researches on the relations between mosquitos and malaria, which have formed the subject of several notes in NATURE. Suffice it here to say that these researches have led Grassi, with the co-operation of G. Bastianelli, A. Bignami, and A. Dionisi to trace the further stages of the development of the malarial parasite within the body of the gnat *Anopheles claviger*, a work which must certainly result in facilitating the prevention of this dangerous disease in Italy. A series of papers on the morphology of Diplopods have been presented by F. Silvestri. The late A. Costa commenced an investigation on the reciprocal actions of certain animal toxins, based on the fact that the sting of certain Hymenoptera (*Scolia*) has the remarkable property of allaying the irritation due to a scorpion's sting. P. Pavesi chronicles the capture of a fish (*Coregonus Schinzii Helveticus*) near the mouth of the Ticino, probably carried down from Lago Maggiore. L. Maggi has made an extended study of the comparative anatomy of the skull, tracing the homology and homotopy of certain bones from the ichthyosaurus up to man.

Among physiological and histological papers, interest attaches to Albini's considerations on the nutritive value of whole-meal bread, which seem to demonstrate that this bread is inferior in nutritive matter to ordinary bread, besides having the disadvantage of containing an excessive quantity of indigestible matter formed of the harder parts of the pericarp of the grains. A. Montuori has investigated the formation of hæmobilin. Golgi has noted two remarkable peculiarities of the nerve-cell. Monti deals with the preservation of museum specimens, and with the pathology of nerve-fibres in anæmia, in embolism, in congestion, in hydræmia, in malaria, in poisoning, and in inflammation. The conversion of starch into sugar during digestion in the stomach is dealt with at some length by E. Oehl. Marenghi has studied the regeneration of nervous fibres in cut nerves; M. Jatta, the genesis of fibrin in pleural inflammation; and D. Baldi has applied the Baubigny process to discover the presence of bromine in thyroids.

Italian science has lost the following workers during the year 1898: Pacifico Barilari, engineer, for many years president of the Council of Public Works in Rome; Giuseppe Gibelli, professor of botany in the Royal University of Turin; A. Costa, the author of numerous papers on entomology dealing with Amphipoda, Hymenoptera, and especially with Italian saw-flies; Teodoro Carnel, botanist, of Florence; and Dr. Eugenio Bettoni, director of the Royal Piscicultural Station in Brescia.

A condensed review, such as the present, would not be complete without some reference to the long array of papers—many of them of the greatest interest to specialists—which want of space prevents us from enumerating individually, but which are none the less worthy of consideration. G. H. BRYAN.

## *HIGHER EDUCATION IN PARIS.*[1]

THE report of the Senate of the University of Paris, drawn up by Prof. Moissan, and presented to the Minister of Public Instruction in December last, gives abundant evidence of the excellent provision for higher education in Paris. It is gratifying to observe the importance attached, by State authorities in France, to the opinions held by eminent men of science on the subject of education. The record of a splendid year's work which is here brought together is proof enough, were any needed, that nothing but good can result when men distinguished in science exert their influence on Councils responsible for the administration of education.

On July 10, 1896, the new University of Paris was endowed by law with a large measure of autonomy. After the period of transition, which naturally followed the inauguration of the new University, the results of self-government have proved completely satisfactory, as the work accomplished during the school-year 1897-8 amply demonstrates. Since 1896 new chairs have been established, new courses of instruction have been formulated, new laboratories have been furnished, and the provisions for practical work have been extended in several directions. The Senate has considered many questions directly affecting their relations with the students, and has endeavoured to interest the general public in the work and development of the University. It is recognised that the University should be a national institution, and that substantial progress can only be assured by an association of effort on the part of the whole body of professors and the public.

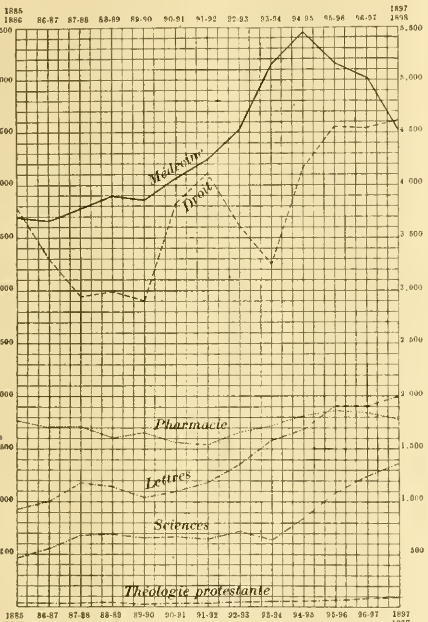
*Number of Students, &c.*—The following table shows the number of students in the various faculties for two years, that especially dealt with in the present report and the year immediately preceding:—

| | 1897-8. | 1896-7. |
|---|---|---|
| Faculty of Protestant Theology | 95 | 77 |
| Faculty of Law | 4607 | 4549 |
| Faculty of Medicine | 4495 | 5015 |
| Faculty of Science | 1370 | 1243 |
| Faculty of Letters | 1989 | 1904 |
| Higher School of Pharmacy | 1790 | 1845 |
| | 14,346 | 14,633 |

[1] Rapport du Conseil de l'Université de Paris. (Année Scolaire 1897-1898.)

The decrease in the number of students studying medicine is more apparent than real, the method of classifying and certain natural fluctuations being sufficient to explain it. The increase in the numbers taking law, science and literature has been steadily maintained for some years, though, as the accompanying curves show, there have been temporary unimportant diminutions.

The number of foreign students at the University during 1897–8 was 1258, of whom 110, representing eighteen nationalities, were studying science. There were 250 women students, of whom 187 were foreigners. The numbers of bachelor's diplomas awarded in the faculty of Science for the two years referred to above



Number of students in the various Faculties of the Paris University since 1885.

were 947 and 795 respectively. These included several branches, as follows:—

| | | 1897–8. | 1896–7. |
|---|---|---|---|
| Faculty of Science. | Classical (Literature—Mathematics) ... | 585 | 444 |
| | Modern (Literature—Sciences) ... ... | 197 | 203 |
| | Modern (Literature—Mathematics) ... | 165 | 148 |
| | | 947 | 795 |

It is interesting to note that fifty scholarships are offered by the State in science, out of a total number of 146 in all faculties. No science scholarships are provided either by the city authorities or by private individuals, though fifty-six, spread over the other faculties, are available from these sources.

*The Doctorate of the University of Paris.*—Recognising that the systems of secondary education in other countries differ from those of France, and that in consequence foreigners are not able to rapidly pass the examinations necessary for the diploma of bachelor, which have hitherto been compulsory before proceeding to the doctorate, the Council of the University of Paris has modified the regulations governing the bestowal of its doctorate as far as foreigners are concerned. As the report makes clear, the imperfect knowledge of French and French literature possessed by most of these foreign students has also been taken into account, and for the future the bachelorship will not be considered indispensable. A foreigner may, without having taken the degree of bachelor at the University of Paris, be very strong in some subject or other. Why, asks Prof. Moissan, should he be prevented from taking the doctorate? The Council wish, as they say, to open their University to every type of mind; two things only are demanded of the aspirant to the doctorate—intelligence and work. No kind of official stamp will be insisted upon. This will lead the way, the Council very properly think, to what they regard as their chief duty the encouragement of scientific investigation. There is a large number of students at present in the science laboratories of the University itself, as well as those of the Pharmaceutical School, who are preparing theses for the new doctorate.

*New Gifts to the University.*—Many important gifts and bequests have been made to the University during the year.

(1) *Charles Legroux Prize.*—A donation of 10,000 francs, made by Madame Legroux, for the establishment of a quinquennial prize, to be awarded to the best work on the treatment and causes of diabetes.

(2) *Marjolin Legacy.*—The proceeds from property to be applied to paying the fees, for further terms, of French students of medicine who have been characterised for their zeal and exactness.

(3) *Mercet Donation.*—M. Émile Louis Mercet has given an annual amount of 3000 francs for six years, to be applied towards the salary of a secretary for a department of the Sorbonne.

(4) *Countess Chambrun Foundation.*—An annual gift of 5000 francs for thirty years towards the foundation of a course of study in social economics.

(5) *Anonymous Gift of* 50,000 *francs.*—This bequest was remitted to the Council by M. Lavisse. It brings an annual revenue of 2000 francs, which is to be devoted towards alleviating the needs of deserving French or foreign students.

(6) *Anonymous Gift of* 75,000 *francs for Travelling Scholarships.*—The anonymous donor proposes, if necessary, to renew this gift annually for three or four years. It is to be devoted to founding five travelling scholarships, each of the value of 15,000 francs. Two are to go to old students of the École normale supérieure, three to old students of the University. The choice of suitable students will be in the hands of the Council of the University on the report of a commission appointed by the Rector. The scholarship holders will employ some fifteen months in travelling round the world with the object of studying the social conditions, forms of government, &c., of different countries.

Of other important questions, such, for example, as an account of the work carried on in the laboratories and hospitals, the researches which have been made, and the technical applications arising therefrom, the errors rectified during the year, M. Moissan says space will permit him to say nothing. But there is more than enough in this interesting report to show that the University of Paris, with its 116 professors, to say nothing of lecturers, laboratory directors, and experimentalists, is doing a good work, and that its constitution in 1896, out of the older University of France, was fully justified. When it is borne in mind, moreover, that side by side with the instruction in science which is going on in the University, Paris possesses such large schools as the College of France, the Natural History Museum, the School of

Mines, the Normal School, the Polytechnic, the School of Fine Arts, the Pasteur Institute, the Central School and others, all engaged in a greater or less degree in imparting and advancing scientific knowledge, it will be seen that the provision for higher technical instruction in Paris is of the most satisfactory kind.

A. T. SIMMONS.

## *THE EXHIBITION OF RECENT ACQUISITIONS AT THE NATURAL HISTORY MUSEUM.*

It has already become recognised that collections of objects intended to be exhibited to the general public should be presented in such a way as to enable the visitor to obtain some systematised information. This one takes to be the so-called educational side of the question. Museum curators, however, although by necessity extremely conservative, are beginning to find themselves in a position not very different from that of the popular lecturer or writer of the day. Unless these have something new to offer, be it only the method, so to speak, of marketing their wares, they will fail to arrest the attention which, when once directed in the sought-for way, may never again be lost.

The curator, it must be pointed out, is in a worse plight than the others, for the lecturer's audience is a varying one, and the writer can change his public; while the museum, as one is accustomed to it, is a fixture. Again, whereas the hearing of a lecture or enjoyment of an article usually presupposes some amount of expenditure upon the part of the hearer or reader, on the other hand most museums are free; and there is a good deal of truth in the saying that what is paid for is appreciated more than that which is had for nothing.

A little living interest must always be an advantage to a museum, and there seems some likelihood that Prof. Ray Lankester's infusing of some into the natural history side of the British Museum may mark the beginning of a new era there.

Possibly the new departure may be of more direct value to the general public, who only pays for the Museum, than to the specialists who use the building; but let us consider the matter in detail.

The arched recesses opening out of the entrance hall have hitherto been assigned to the index collections. These were intended as a biological introduction to the main groups represented in detail in the galleries, but they have never been absolutely completed. Recently, indeed, some of the specimens have been taken away, possibly to reappear in a more suitable position at the head of the series they elucidate. More to the point is the fact, that their place in the last alcove but one on the right-hand side is now taken by "specimens recently acquired."

The collection which first arrests attention illustrates the remarkable molluscan fauna of Lake Tanganyika. There are three series of shells, two of which show the freshwater molluscs of the general type which inhabit the African lakes, as illustrated by representatives from Lakes Nyassa and Tanganyika. The third consists of shells from the latter piece of water, which belong to the series called halolimnic, by Mr. J. E. S. Moore, who has done so much to add to our knowledge of the Tanganyikan fauna, and who has started this month upon a second expedition to the Great Lakes of Africa. This naturalist has shown that the shells in question are almost identical with well-known Jurassic forms, and the chief interest surrounding this exhibit is that in many cases, side by side with the examples collected by Mr. Moore, are their fossil representatives. This reminds one forcibly of the arbitrary line drawn in the arrangement of the Museum between fossil and recent genera; but this by the way. As instances of the pairs of similar species might be quoted:

| Tanganyika. | Jurassic. |
|---|---|
| *Chytra kirkii.* | *Onustus ornatissimus*, Burton Bradstock. |
| *Bathanalia irridescens.* | *Amberleya orbignyana*, near Yeovil. |
| *Pseudomelania damoni.* | *Purpurina bellona*, Bradford Abbas. |
| *Limnotrochus thomsoni.* | *Littorina dorsetensis*, near Yeovil. |
| *Melania admirabilis.* | *Cerithium subscalariforme*, Bradford Abbas. |

Possibly the most striking exhibit is the collection of siliceous hexactinellid sponges dredged from Saguma Bay in Japan, and purchased by the Museum: many types and some of the finest examples yet known are among the number. They come from depths varying from 80 to 300 fathoms, and mention might be made of the fine *Euplectella imperialis* and *Rhabdocalyptus victor*, while the specimen of *Chaunoplectella cavernosa* is particularly beautiful.

The rare birds' skins presented by Dr. Moreno, the director of the Museum of La Plata, are as they were received. Indeed, it is rather agreeable to see exhibited in the Museum something which is not absolutely spick and span. An albino song-thrush from Argyll, presented by Colonel Edward Malcolm, finds a place by an example of one of the four recent species of *Pleurotomaria*, viz. *berichii*, all very rare and valuable, and the only living representatives of a genus once a thousand strong. The particular specimen contained the soft parts, and we are looking forward to an interesting paper based upon them from Mr. Martin Woodward, who gave a description of the radula to the Malacological Society the other day. A series of models illustrating the development of the chick within the egg attracted much attention on Easter Monday, as appertaining to something more or less familiar to the crowds whose acquaintance with oranges was even closer, judging from the heaps of peel not wholly left outside the building.

A formidable array of bottles contains a large collection of crustaceans exchanged with the Paris Museum, and chiefly obtained during the *Talisman* and *Travailleur* expeditions. Following close up, there is a second display of members of the same class from the Indian Museum. Lastly, must be mentioned several series of fish: one collected by Mr. Moore in the same lake as the shells; another representing a selection of the remarkable forms inhabiting the River Congo, presented by the Secretary of State for the Congo Free State, and recently described by Mr. G. A. Boulenger, with annals of the museum belonging to that republic. Many peculiarities of structure are to be met with; for instance, the curved snouts of the species belonging to the genus *Gnathonemus*, from which they take such names as *curvirostratus elephas* and *rhyncophorus*. The large teeth, too, of *Hydrocyon goliath* are most striking, fitting as they do between a pair of those in the opposite jaw, and coming to lie in deep grooves beyond their bases.

Two specimens of *Lepidosiren paradoxa*, sent by Mr. Graham Kerr from Paraguayan Chaco, complete the present list of the new exhibits.

Neglecting the actualities and possibilities of the Museum as a centre for research, it is primarily a storehouse in which everything, so far as space allows, is exhibited; a fact that enables the collector to name his specimens without unduly taking up the time of the staff. Secondly, the educational idea has been added to, but not combined with, this; while the popular interest will bear development, and it remains for the new director to work the various lines of usefulness into a well-balanced and harmonious whole.

WILFRED MARK WEBB.

## SURGEON-MAJOR G. C. WALLICH, M.D.

THERE passed away in his eighty-fourth year, at Nottingham Place, Marylebone, on March 31, George Charles Wallich, L.R.C.S. Ed., Surgeon-Major on the Retired List of Her Majesty's Indian Army; and in his decease zoology has lost an honest devotee whose work has left its impress on the progress of the science. He was the eldest son of Nathaniel Wallich, F.R.S., Knight of the Royal Danish Order of Dannebrog, distinguished during the early half of the century for his work on Indian botany, he being superintendent of the Botanic Gardens, Calcutta, where G. C. Wallich was born in November 1815. He was educated at Beverley in Yorkshire, at Reading Grammar School, and at King's College, Aberdeen, and the Edinburgh University, where he graduated M.D. in 1836, becoming the following year a Licentiate of the Royal College of Surgeons of that city. In 1838 he entered the Indian Army, and served as assistant-superintending surgeon in the Sutlej Campaign, and in 1847 he went through the Punjab wars, receiving the medal in commemoration of each. Eight years later he acted as field-surgeon during the Sonthal Campaign; and, invalided home in 1857, he two years afterwards settled at Guernsey, and afterwards at Kensington.

His scientific career dates from 1844, in which year he produced a paper dealing with "Some experiments tending to prove that the venous circulation is dependent on a vital act." His period of active and most continuous investigation, however, dates from the years 1858 to 1883, and his forty-eight papers produced during that time mostly deal with important questions of structure and distribution of the Protozoa, and allied organisms especially conspicuous in the leading topics in the marine biology of the time. Those which remain were devoted to the allied consideration of questions bearing on the formation of the sedimentary deposits formed by the lower organisms in both passing and past periods of the world's history, with here and there an occasional departure into the higher groups of animals. It was in the year 1860 that Wallich started upon the line of inquiry by which his authority was established. Being recommended by Sir R. Murchison and Huxley for the post of naturalist to H.M. *Bulldog*, about to survey the ground for the North Atlantic cable between Great Britain and America, he sailed under command of Sir F. L. McClintock, R.N., in June 1860, returning to London in November of that year. As the result of this voyage, he was the first to demonstrate that ocean depths below 1000 fathoms were actually inhabited. The facts concerning temperature, pressure, and the general conditions at these depths at the time known and surmised had led to the belief that animal life was thereat impossible, and Wallich, in proving the contrary, laid the foundations of our modern deep-sea research. Working out the soundings obtained during this memorable voyage, he later published the first part of a projected book, entitled "The North Atlantic Sea Bed," by which he became famous. Although never completed, this will remain a standard work in the literature of deep-sea investigation, and a lasting testimony to its author's acumen and powers of observation. While most fascinated by the geographical and lithological aspects of his task, Wallich was by no means neglectful of the more purely biological, and of the structure and physiological manifestations of the individual organism. Contemporary of the elder Carpenter, of Allman, and others who early in the latter half of the present century essayed the pioneer's task of unravelling the mysteries of life as revealed in their essence by the unicellular organism, his contributions towards the determination of the excretory nature of the contractile vacuole, and his attempt, at a period at which our micro-chemical methods were in their infancy, to differentiate the nucleus by means of an electric discharge, will always be interesting chapters in the history of physiological inquiry. Trenchant in his literary style, prone to discussion, we find him in controversy with his contemporary workers—conspicuously as concerning his views upon the "Bathybius," which Huxley, in later years, admitted his "bogey," and the Coccospheres, upon which recent investigation has proved his views to have been largely sound. He did well in his time, and his work will endure.

While neither distinction nor special recognition were meted out to him during the active years of his life, he was in 1898 awarded the Gold Medal of the Linnean Society of London, "in recognition of his researches into the problems connected with bathybial and pelagic life." He was an Hon. Fellow of the Microscopical Society, and a Corresponding Member of the Royal Society of Liége.

## NOTES.

IT is announced that, in accordance with the amended Standard Time Act, Adelaide time was advanced half an hour at midnight on Sunday.

WE learn from the *Astronomische Nachrichten* that the Fürstlich Jablonowskisebe Gesellschaft offers for 1902 a prize of 1000 marks for an essay bearing on Poincaré's investigations of Neumann's method of the arithmetic mean. The scope of the essays is defined by the society as follows:—That the investigations contained in Poincaré's work of 1896, entitled "La méthode de Neumann et le problème de Dirichlet," might be materially developed in some direction or other.

PARTICULARS concerning the work of the Belgian Antarctic Expedition have been given to the Brussels Geographical Society by Lieut. Gerlache, commander of the expedition. The *Times* gives the following summary of Lieut. Gerlache's report: The expedition left St. John's Bay on January 14, 1898, and on the 21st explored the South Shetland Islands. On January 15, in 55° 5′ south latitude and 65° 19′ west longitude, soundings to the depth of 4040 metres were taken. The *Belgica* left on the 23rd for Hughes Bay, discovering a strait separating the lands of the east from an unknown archipelago. The land to the east was named Danco Land. Magnetic observations were made and interesting botanical, geological, and photographic results were obtained. On February 13 the *Belgica* went in the direction of Alexander I Land, exploring the belt of bank ice towards the west. On March 10 the ship became fast in the ice in latitude 71° 34′, longitude 89° 10′. The sun disappeared on May 17, and there was continual night until July 21. M. Danco died on June 5, and his remains were deposited in a tomb of ice. The *Belgica*, after leaving her winter quarters, again became fast in the ice in 103° west longitude. She reached open water on March 14. The expedition made successful magnetic and meteorological observations, and obtained collections of pelagic and deep-sea fauna and samples of submarine sediments. On February 26 Black Island was explored, and on the following day the *Belgica* entered the Cockburn Channel, arriving at Punta Arenas, in Patagonia, on March 28.

AT the annual meeting of the members of the Royal Institution held on Monday, the Duke of Northumberland, President, presiding, it was announced that next month the Institution will complete one hundred years of its existence, the first meeting of its members in the building in Albemarle Street having been held on June 5, 1799. The managers have decided that this event, so interesting and memorable in the life of the Institution and in the history of science in this country, shall be duly celebrated.

They have, therefore, arranged for the delivery of two Commemoration Lectures. The first of these lectures will be delivered at three o'clock on Tuesday, June 6, by Lord Rayleigh, when His Royal Highness the Prince of Wales, Vice-Patron of the Institution, will preside and receive the honorary members; the second of these lectures will be delivered at nine o'clock on Wednesday evening, June 7, by Prof. Dewar, when His Grace the Duke of Northumberland, President of the Institution, will preside. It was further announced that the Lord Mayor has consented to give a reception to the members, foreign guests, and representative men, at the Mansion House, on the evening of Tuesday, June 6.

IN a brief reference to the recent scientific work of the Royal Institution, Prof. Dewar announced on Monday that having obtained liquid hydrogen in considerable quantity, he has directly determined its temperature and other physical constants, finding its boiling point to be much lower than was previously supposed, namely 20° above the zero of absolute temperature, and attaining by exhaustion a temperature of only 15° absolute. Pending the discovery in quantity of some yet lighter gas, there are no means within sight of bridging this gap and reaching the zero point. Prof. Dewar also took occasion to give a warning against the exaggerated accounts of the properties of liquid air, which, originating in America, have found their way into popular magazines in this country.

THE Trustees of the National Portrait Gallery have received, under the will of the late Colonel John Barrow, F.R.S., formerly of the Admiralty, a bequest of a series of portraits, painted for Colonel Barrow by Mr. Stephen Pearce, relating to the various expeditions in search of Sir John Franklin. The portraits comprise a large portrait-group representing "The Arctic Council" "discussing a plan of search for Sir John Franklin"; four large half-length portraits, representing Sir Robert McClure, Sir Leopold McClintock, Captain Penny, and Sir George Nares, each in the dress worn by him in the Arctic regions; fifteen small portraits of Sir Richard Collinson, Sir Henry Kellett, Sir Edward Belcher, Sir Edward Inglefield, Dr. John Rae, Captain Rochfort-Maguire, Captain J. E. Moore, Dr. Robert McCormick, Lient. J. Stewart, Lieut. Bellot, Sir Horatio T. Austin, Admiral Sherard Osborn, Dr. William Kennedy, Sir Leopold McClintock, and Sir Erasmus Ommanney.

THE Report of the Council of the Zoological Society, read at the seventieth anniversary meeting held on Friday last, stated that the number of Fellows on December 31, 1898, was 3185, showing an increase of twenty-seven during the past year, and that the number of Fellows on the roll of the Society was in excess of what it had been in any year since 1885. The principal new buildings erected in the Society's Gardens in 1898 were the Fellows' tea pavilion, the new llama-house, and the new zebra-house, all of which are well adapted to the purpose for which they were intended. The number of visitors to the Gardens was 710,948. The number of animals living in the Gardens at the end of the year was 2656, of which 818 were mammals, 1363 birds, and 475 reptiles and batrachians. Dr. John Anderson, F.R.S., Mr. W. E. de Winton, Dr. Charles H. Gatty, Sir Hugh Low, G.C.M.G., and Dr. Henry Woodward, F.R.S., were elected into the Council in the place of the retiring members, and his Grace the Duke of Bedford and Mr. Edward N. Buxton, elected into the Council since the last anniversary, were re-elected; also Sir William H. Flower, K.C.B., F.R.S., was re-elected President, Mr. Charles Drummond, Treasurer, and Dr. P. L. Sclater, F.R.S., as Secretary.

AT the annual general meeting of the Institution of Civil Engineers, held on April 26, Mr. W. H. Preece, C.B., President, in the chair, the result of the ballot for the election of officers was declared as follows: President, Sir Douglas Fox; vice-presidents, Mr. James Mansergh, Sir William White, K.C.B., Mr. Charles Hawksley, and Mr. John Clarke Hawkshaw; other members of Council, Mr. James Barton (Dundalk), Mr. Horace Bell, Sir Alexander Binnie, Dr. Henry Taylor Bovey, Mr. T. Forster Brown, Mr. W. R. Galbraith, Mr. George Graham, Mr. G. H. Hill, Mr. J. C. Inglis, Mr. Alexander Izat, Dr. Alex. B. W. Kennedy, F.R.S., Sir James Kitson, Bart., Mr. Anthony George Lyster, Mr. John Allen McDonald, Mr. E. Pritchard Martin, Mr. William Matthews, Sir Guilford Molesworth, K.C.I.E., Sir Andrew Noble, K.C.B., Mr. Alexander Siemens, Mr. Thomas Stewart, Mr. John I. Thornycroft, F.R.S., Mr. William Thwaites, Mr. F. W. Webb, and Sir E. Leader Williams.

THE Royal College of Surgeons of England has unsuccessfully appealed against the decision of the Court of Queen's Bench upon the subject of its liability to property duty in respect of part of the property held by it for the public objects of the institution. A strong protest is made against this result in the *Lancet*. It is pointed out that the College is a body incorporated by Royal Charter, the object being the "benefit of the common weal of this kingdom by the promotion of the art and science of surgery and the due promotion and encouragement of the study and practice of the said art and science of surgery." To the attainment of this object all its funds are legally appropriated and actually applied; nevertheless, the courts have decided to exclude the College from the benefits of an exception created by the Act of Parliament in favour of "any property legally appropriated and applied for . . . the promotion of science." The decision distinguishes between the museum and the library in Lincoln's Inn, and while it protects the museum as being devoted to the promotion of the science of surgery, the library is regarded as for the private convenience or advantage of the members of the College. The *Lancet* points out that eight or nine years ago the question arose as to whether the Institution of Civil Engineers was, in circumstances almost precisely parallel to those of the Royal College of Surgeons at the present day, liable to the same duty. Fortunately for that institution, the House of Lords held that applied science, no less than the pure sciences, fell within the meaning of the Act, and sustained the claim to exemption in spite of the professional eminence and social success of its members. The Royal College of Surgeons is less fortunate in its present situation.

THE death is announced of Dr. C. Brongniart, Paris, distinguished by his entomological works, and more especially by his memoir on fossil insects of the Primary period.

ACCORDING to a despatch from St. Louis a very destructive cyclone swept over Kirksville, Missouri, on Thursday last. The storm broke about 6.30 p.m. with great fury, sweeping a path a quarter of a mile broad through the eastern portion of the town, four hundred buildings being demolished. Heavy rain followed, accompanied by intense darkness.

DR. LUDWIG BÜCHNER, of Darmstadt, the author of "Kraft und Stoff" (1855), a work which did much to popularise scientific materialism in Germany, died on Monday, at seventy-five years of age. Dr. Büchner was one of the most meritorious popularisers of natural science in Germany, and greatly assisted in diffusing a knowledge of the Darwinian theories in the Fatherland.

THE death is announced of Mr. Charles Leeson Prince, of Crowborough, Sussex, whose meteorological work has on several occasions been referred to in these columns. Mr. Prince was a member of the Royal College of Surgeons, and a licentiate of the Society of Apothecaries. For many years

he had taken great interest in all questions relating to meteorology. He was a Fellow of the Royal Astronomical and of the Meteorological Societies, and a member of the Scottish Meteorological Society, and the author of several papers on the meteorology of Uckfield and Crowborough Hill.

Mr. Akers-Douglas, M.P., the First Commissioner of Works, speaking at Whitstable-on-Sea on Thursday last, referred to the favourable reports by the medical inspectors on the Whitstable oyster beds, and said that the promised legislation has not been forgotten. The President of the Local Government Board, with a desire to set at rest the fears regarding the eating of oysters, and to protect a *bona-fide* industry, is about to introduce a measure providing for the inspection of oyster layings, prohibiting removal from insanitary grounds, and regulating the importation of foreign oysters from suspected districts.

Reuter reports that the President of the Geographical Society at Christiania has received a letter from M. Borchgrevink, dated Cape Adair, Victoria Land, February 28, in which he says:—"I have now landed on the great Australian continent with staff, instruments, and seventy-five dogs. The greatest discipline has prevailed throughout."

From the current number of the U.S. *Monthly Weather Review* (for December last) we learn that the important decision has been taken of correcting all the published barometrical values for gravity from January 1, 1899. This change has been found necessary owing to the recent extensions of the Weather Bureau in the West Indies and along the South American coast. The reduction to standard temperature has been practised for the last sixty years, but the reduction to standard gravity has been applied only in special cases; and although the amount of the correction is now usually stated at the head of meteorological tables in the same way as the latitude and longitude and height above sea-level, the general application of the correction to the individual readings has been delayed until a concert of action among all nations could be arrived at. Its importance, however, has been recognised by various meteorological conferences. In the latitude of London the correction to standard gravity of latitude 45° amounts to about + ·02 inch.

The Report of the Kew Observatory Committee of the Royal Society has been published for the year 1898. In the section referring to terrestrial magnetism, it is stated that two magnetic storms, or periods of considerable disturbance of the needles were registered, viz. on March 14–15 and on September 9–10. The first storm was the largest recorded since August 1894, and both were presumably associated with the aurora simultaneously seen in the British Isles. One of Prof. J. Milne's seismographs, intended to measure the tilting of the ground along an east–west line, was erected in the early part of the year. The largest tremors were recorded on June 29, August 31, and November 17. Among the experimental work carried on during the year may be specially mentioned that relating to atmospheric electricity, aneroid barometers, and platinum and mercurial thermometry. The verification of instruments of various kinds has steadily increased, the number tested during the year exceeding 24,000. Although the number of watches sent for trial was less than in the previous year, the high standard referred to in previous reports has been maintained. During the year, various schemes have been promoted in connection with electric tramways in the neighbourhood of the observatory. The Committee state that whilst everything has been done, as far as can be foreseen, to protect the magnetographs, it is impossible to contemplate the future without some misgivings. The proposed establishment of a National Physical Laboratory will, in all probability, greatly extend the usefulness of the Kew Observatory; the arrangements were not completed before the close of the year 1898.

The members of the German Deep Sea Expedition arrived in Hamburg on Saturday, on board the *Valdivia*, after nine months' absence. They were welcomed (the *Times* reports) by the Imperial Secretary of State for the Interior, Count von Posadowsky, the Saxon Minister of Education, Baron von Seydewitz, Prof. Drygalski, who will be the leader of the German Antarctic expedition, and a large number of the representatives of the scientific world. At a banquet given in the dining-hall of the offices of the Hamburg-American Line, Count Posadowsky welcomed the members of the expedition in a speech in which he referred to the interest manifested by the Emperor in the expedition and in all seafaring projects. This was not due solely to his Majesty's personal inclinations, but resulted from his profound recognition of the importance of these subjects for the future of Germany. A telegram was read in which the Emperor expressed his satisfaction at the success of the expedition.

Dr. R. H. Scott, F.R.S., gives in the *Quarterly Journal of the Royal Meteorological Society*, dated January 1899 and just issued, a translation of the important paper on the diurnal oscillation of the barometer, contributed by Dr. Julius Hann to the *Meteorologische Zeitschrift* for October 1898. Meteorologists unfamiliar with the German language will be glad to have this English version of Dr. Hann's contribution to the theory of the daily barometric oscillations.

As an indication of the character of the season, Mr. W. Baylor Hartland, writing from Cork, says his son saw swallows on Wednesday last, April 26, at Ard-Cairn. On Thursday he himself saw a pair of corncrakes nestling among some daffodil beds. Mr. Hartland adds: "If this had occurred in a field of rye, wheat, rye-grass, or vetches, I should not have noticed it. But for the birds to nestle within the foliage of broad plantations of daffodils, planted for commercial purposes in Ireland, never before happened in the Green Isle. I have grown them for eighteen years, but the foliage this year is so luxuriant, I suppose the birds were attracted by its shelter."

A Parliamentary Return just issued shows that between the date of the passing of the Vaccination Act on August 12 and December 31, 1898, the number of certificates of conscientious objection received by the vaccination officers was 203,413, and that the number of children to whom such certificates related was 230,147.

It is stated by the *Allgemeine Militär-Zeitung* that the aluminium steerable balloon invented by Count Zeppelin will very probably make its first ascent at the beginning of July. The ascent will take place above Lake Constance. In order that the balloon may rise clear of trees and buildings, a platform has been built in the lake on pontoons, at about 700 metres from the shore, where the apparatus for raising the balloon will be placed.

In a paper on the treatment of refractory silver ores by lixiviation, read by Mr. Breakell at a recent meeting of the Institution of Mining Engineers, some results are given which bear strong testimony to the value of Russell's modification of the hyposulphite process. Experiments are described proving that the presence of only 0·2 per cent. of copper increases the volatilisation loss of silver in chloridising roasting. In one case the loss was raised from 0·5 to 3·6 ounces of silver per ton by the addition of this amount of copper. On the other hand, metallic silver and sulphide of silver, which are always present, especially in badly roasted charges, are readily dissolved

by hyposulphite solutions containing copper, though not rapidly acted on in its absence. It follows that the presence of copper should be avoided in the furnace charge, and that it may be added with advantage in the later stages of the process.

The old view that insects, with all the lower animals, were created for man's benefit cannot reasonably be held at the present time, but it must, nevertheless, not be forgotten that there are very many beneficial as well as injurious insects. Dr. L. O. Howard has recently summed up the good and bad qualities of insects so far as it is possible to do, and he finds that the insects of 116 families are beneficial, and the insects of 113 families are injurious, while those of 71 families are both beneficial and harmful or their functions have not been determined. The injurious insects are made up of 112 families which feed upon cultivated or useful plants, and one family the members of which are parasitic upon warm-blooded animals. Of the beneficial insects, those of 79 families are valuable as preying upon other insects, 32 families are of service as scavengers, two families as pollenisers, and three families as forming food for food fishes.

Prof. F. E. Schulze, of Berlin, the general editor of the important new German work, "Das Tierreich," which is in course of publication by Messrs. R. Friedländer and Son, has obtained the services of Prof. Kretschmer, of Marburg, for the preparation of a series of rules for the formation and pronunciation of zoological and botanical names upon classical and orthodox principles. These rules seem to be excellent in every way, and will, we trust, be strictly followed by the numerous contributors to "Das Tierreich." In America, we regret to say, a small school of zoologists has arisen who prefer to spell and pronounce names *in*correctly, following literally the mistakes often made by their original propounders. This pestilent heresy has, we are glad to say, not met with much support in Europe, and we hope that Prof. Kretschmer's rules will assist in suppressing it.

In the "Report of the Entomological Department of the New Jersey Agricultural College Experiment Station for the year 1898," Dr. John B. Smith calls attention to the interesting and perhaps important fact that the San José scale now begins breeding later than when it first came under his observation, and that the rate of increase before midsummer is materially less than in the past, the period of greatest increase being now in September. It is evident that the introduced pest is endeavouring to accommodate itself to its new surroundings, and it will be interesting to see whether it succeeds or fails. If it fails, its automatic extinction will be a mere matter of time, though it is quite possible that it may be capable of producing a great amount of harm before that time arrives.

A recent number of the *Cape Agricultural Journal* contains a report of an address given by Dr. Edington on the artificial use of a particular fungus, said to be parasitic to locusts, for the destruction of the latter. The results so far obtained with the fungus in question appear to be at considerable variance, some farmers stating that they have derived great benefit from its application, whilst others assert as positively that it has been of no use whatever. A great deal must of necessity depend upon the circumstances in which this, together with other such similar living-destroying agencies, are employed, and Dr. Edington, in the course of his lecture, pointed out what he considered the best methods for promoting the successful use of this fungus. If locusts can be destroyed in so simple a manner as this is described to be, the gain to the Cape farmers will be enormous, and at any rate means should be adopted so that its use may become more widely known, and more extensive trials given to it. The use of fungi for the destruction of pests is being tried in America, where the white muscardine fungus, *Sporotrichum globuliferum*, has been largely employed during the last few years to check the injurious over-production of the chinch-bug. Mr. Benjamin Duggar, of the Cornell Agricultural Experiment Station, has, however, been recently making a careful study of this organism in relation to the insect in question, and has come to the conclusion that, although it is undoubtedly parasitic at times, it is not sufficiently efficient to enable it to be artificially employed with economic success. It is obvious that to obtain trustworthy data on this subject, many and very carefully conducted investigations must be carried out. It is to be hoped that Dr. Edington will be able to give the locust-problem the time and attention which it requires to enable scientific conclusions to be drawn as to the economic value of the fungus he recommends in destroying locusts.

The current number of the *Journal of the Sanitary Institute* continues the reports of papers read at the congress held in Birmingham last year. Amongst them we note a useful little address given by Dr. Mary D. Sturge in the Section devoted to domestic hygiene, entitled "The Claims of Childhood." Whilst emphasising the responsibilities of parents towards their offspring, the writer also points out the necessity of our following the example of France in getting legislative measures directed towards checking the growing use of tobacco amongst young boys. In Norway only last year, it appears, stringent laws were passed forbidding the sale of tobacco to lads under sixteen, and prohibiting their smoking in the streets. Although the municipal authorities in most of our large crowded cities are alive to the duty of modifying as far as possible the unfavourable conditions under which children are of necessity reared, yet much remains still to be done. Dr. Sturge, amongst other matters, calls attention to the smoke-nuisance, and indulges in the hope that some day legislative steps will be taken whereby it will be controlled, and incidentally tells us that in the Tudor period a law existed ordering Londoners to burn nothing but wood during the time that Parliament was sitting, in order that the health of the country squires who came to town might not be impaired!

Mr. William H. Dall has prepared a useful table of the North American Tertiary horizons, correlated with one another and with those of Western Europe (Eighteenth Annual Report of the U.S. Geological Survey, 1898).

The geology of the eastern part of Texas, with reference to the artesian wells, forms the subject of an essay by Mr. Robert T. Hill and Mr. T. Wayland Vaughan (Eighteenth Annual Report of the U.S. Geological Survey).

MM. E. Piette and J. de la Porterie describe some prehistoric remains from excavations at Brassempouy, south-east of Dax, Department of Landes. Drawings on bones and various finely-worked implements are figured (*L'Anthropologie*, Paris, tome ix).

The Triassic formation of Connecticut is very fully discussed by Prof. William M. Davis (Eighteenth Annual Report of the U.S. Geological Survey). He treats the subject from three points of view—deposition, deformation, and denudation. The formation comprises a great series of sandstones and shales, with local conglomerates; and it includes in the central division great sheets and dykes of volcanic rock. In mass the formation is of "continental" as opposed to marine origin.

The origin of peneplains is discussed by Prof. W. M. Davis in an article in the *American Geologist* for April. The article is in the main a reply to criticisms by Prof. Tarr. It is maintained that the prolonged results of both marine abrasion and subaerial denudation tend to reduce the land to a base-level (or peneplain)—a nearly featureless plain, a little below or a little above sea-level. It is admitted, with regard to ancient plains of

denudation, that in many instances there seems to be no way of determining how much work was done by the sea, and how much had been previously done by rivers, rain, and similar agencies.

"THE Alkali Soils of the Yellowstone Valley" forms the subject of an essay by Messrs. M. Whitney and T. H. Means (U.S. Department of Agriculture, *Bulletin* No. 14, 1898). In the Western States of America, any excessive accumulation of soluble mineral salts in the soil is popularly spoken of as "alkali." These salts include sodium carbonate, sulphate and chloride, magnesium sulphate and chloride, and occasionally some of the borates. They may be traced to the sandstones, shales, and slaty rocks from which the soils have been derived. Before irrigation was introduced, the salts were present in rather large amounts, but they were well distributed throughout the soil, and not in such large quantities as to be injurious to crops. The injury is due entirely to over-irrigation, and may, in the authors' opinion, be easily remedied.

WE learn from the *Botanical Gazette* that the University of Texas has established a distinct department of botany, which will begin its separate existence with the next college year. The new department will be placed under the charge of Dr. W. L. Bray.

MR. F. J. HANBURY and Rev. E. S. Marshall announce for early publication their long-promised "Flora of Kent," which has been twenty years in preparation. From its variety of soil, its geographical position, and its extended sea and river coast, this will be one of the most interesting and richest county floras of England. There will be two maps, one showing the divisions of the county, and the other coloured geologically; and in the introduction, devoted to the topography of the county, there will be sections assigned to geology and meteorology.

THE study of natural history has been greatly stimulated in this country by the meetings, the excursions, and the publications of local societies. We have before us the *Irish Naturalist* for April, with a paper on the botany of the Great Central Plain of Ireland, by Mr. R. Ll. Praeger, and the conclusion of one on the Brachiopoda and Mollusca of the carboniferous rocks of Ireland, by Dr. A. H. Foord; also the *Halifax Naturalist* for April, containing a paper on the crocus leaf, by Mr. C. E. Mass, and one on the Halifax fish fauna, by Mr. E. D. Wellburn, as well as an instalment of Mr. W. B. Crump's flora of Halifax.

AMONG the more interesting articles in the *Journal of the Royal Horticultural Society* for April is an account of a visit to Naina Tal, Kumaon, the summer residence of the Lieut.-Governor of the North-West Provinces of India; and one on the Botanical Garden at Padua, founded in 1545, and said to be the oldest in the world. It contains some trees of remarkable antiquity, one of *Vitex agnus-castus*, 349, one of *Chamaerops humilis*, 314, and one of *Platanus orientalis*, 219 years old; besides a number that have more than completed the century. Several of these are figured. There is a specimen of *Salisburia adiantifolia*, 148 years old, in which grafts from the female have been inserted on the original male plant, so that it produces both male and female flowers.

MR. BERNARD QUARITCH has published a catalogue containing descriptions of 1781 works of geography, voyages, travels, history of America, Africa, Australasia and Asia, and of books on the languages of America, Africa, and Oceanica, offered for sale by him.

THE fourteenth part of Mr. Oswin A. J. Lee's "Among British Birds in their Nesting Haunts" (Edinburgh: David Douglas) contains ten magnificent plates illustrating the nests of the turtle-dove, barn owl, reed warbler, tree sparrow, stone curlew, partridge, tufted duck, jay, and kingfisher.

FOUR different kinds of species are considered by Mr. O. F. Cook in the *American Naturalist*; they are enumerated as follows: (1) The phylogenetic species, a division or section of a line of biological succession; (2) the insular or segregated species, the living end of a line of the preceding category; (3) the incipient species, preferably known as a sub-species; (4) the artificial species, the result of man's interference in nature. Mr. Cook considers that the designation "species" should be reserved for its original use with the second of these categories, and the use of the popular designation "variety" should be restricted to the fourth. He criticises classification according to "amount of difference," and points out that with this as the only criterion, "fossils, geographic races, and artificially produced varieties are being catalogued miscellaneously and indiscriminately as species."

IN a note communicated to the *Atti dei Lincei*, viii. 5, Dr. A. Pochettino describes the results of certain observations made with acoustic resonators with a view of determining in what manner the modulus of decay is affected: (1) by varying the shape of the aperture, keeping its area constant; (2) by furnishing the aperture with flanges of various sizes; (3) by varying the distance between the resonator and the excitor. Dr. Pochettino finds that by increasing the diameter of the flange the modulus of decay diminishes; or, in the first place, the resonator becomes more capable of reinforcing vibrations of its own period, and at the same time becomes less sensitive to vibrations slightly differing in period, in the second place, the vibrations, when once excited, last longer. The modulus of decay also decreases when the distance between the excitor and resonator is increased. In experimenting with elliptic and circular apertures, the moduli of decay were found to be very nearly equal.

THE second volume of the second edition of Prof. H. Weber's masterly "Lehrbuch der Algebra" has just been published by Messrs. F. Vieweg and Son, Brunswick. The two original volumes have already been reviewed in detail in NATURE (vol. lv. pp. 25 and 481, 1897), so it is unnecessary to do more than announce the completion of the second edition of this standard treatise.—The third edition of "Premiers principes d'Electricité industrielle," by M. Paul Janet, has been published by Messrs. Gauthier-Villars, Paris. The original work contained the substance of lectures delivered in Grenoble in 1892, under the auspices of the municipality of that city. So many advances have taken place in applied electricity since the lectures were given that a number of alterations and additions have been necessary in order to bring the volume up to date.—Mr. William Schooling has revised and extended "Inwood's Tables of Interest and Mortality, for the Purchasing of Estates and Valuation of Properties," and Messrs. Crosby Lockwood and Son have just published the new edition (the twenty-fifth) containing extensive additions made by him The whole work appears to have been very carefully revised, and it now forms an instructive as well as serviceable collection of tables. A table of logarithms of natural numbers has been introduced, and also M. Fédor Thoman's logarithmic tables of compound interest and annuities. From the point of view of practical mathematics, the new edition of "Inwood" is distinctly in advance of the former issues.

THE additions to the Zoological Society's Gardens during the past week include a Feline Dourocouli (*Nyctipithecus vociferans*) from South Brazil, presented by Mrs. Firman; a Common Raccoon (*Procyon lotor*) from North America, a Pine Marten (*Mustela martes*), British, presented by Master Eric Mellin; an Indian Pigmy Goose (*Nettopus coromandelianus*, ♂) from India, presented by H.G. the Duke of Bedford; three Ostriches (*Struthio camelus*, 3 ♀) from Lagos, presented by Mr. G. F. Abadie; a Macqueen's Bustard (*Houbara macqueeni*) from

Western Asia, presented by Mr. B. T. Ffinch; two Double-banded Sand-Grouse (*Pterocles bicinctus*) from Senegal, a Lesser Pin-tailed Sand-Grouse (*Pterocles exustus*) from North Africa, presented by Mr. W. H. St. Quintin; a King Parrakeet (*Aprosmictus cyanopygius*) from Australia, presented by Mr. C. D. Chambers; a Delalande's Gecko (*Tarentola delalandii*) from West Africa, presented by Miss Shenton; a Rhesus Monkey (*Macacus rhesus*, ♂) from India, a Great Kangaroo (*Macropus giganteus*, ♂) from Australia, a Salvadori's Cassowary (*Casuarius salvadorii*), a Blue-necked Cassowary (*Casuarius intensus*) from New Guinea, a Beccari's Cassowary (*Casuarius beccarii*) from South-eastern New Guinea, five Oblong Chelodines (*Chelodina oblonga*) from Australia, a Derbian Sternothere (*Sternothaerus derbianus*) from West Africa, a Blackish Sternothere (*Sternothaerus nigricans*) from Madagascar, two Black-necked Swans (*Cygnus nigricollis*) from Antarctic America, deposited.

## OUR ASTRONOMICAL COLUMN.

COMET 1899 *a* (SWIFT).—This comet having now passed considerably to the west of the sun, it is possible that it may be observed in the eastern sky before sunrise. The following ephemeris is given by Herr H. Kreutz in *Astr. Nach.* (Bd. 149, No. 3556):

*Ephemeris for 12h. Berlin Mean Time.*

| 1899. | R.A. h. m. s. | Decl. ° ′ | Br. |
|---|---|---|---|
| May 4 | 23 57 45 | +25 17·9 | 1·74 |
| 5 | 53 54 | 26 17·3 | 1·69 |
| 6 | 49 53 | 27 19·3 | |
| 7 | 45 41 | 28 24·0 | 1·67 |
| 8 | 41 17 | 29 31·5 | |
| 9 | 36 40 | 30 42·0 | 1·66 |
| 10 | 31 45 | 31 55·7 | |
| 11 | 26 28 | +33 12·7 | 1·66 |

During the week it moves in a north-westerly direction from between Ψ Pegasi and α Andromeda, and is now rapidly decreasing in brightness as it recedes from the sun.

TEMPEL'S COMET (1873 II.).—The following ephemeris is given by M. L. Schulhof in *Ast. Nach.* (Bd. 149, No. 3554):—

*Ephemeris for 12h. Paris Mean Time.*

| 1899. | R.A. h. m. s. | Decl. ° ′ ″ | Br. |
|---|---|---|---|
| May 4 | 18 48 57·0 | −4 42 8 | 0·460 |
| 5 | 50 39·5 | 4 37 57 | |
| 6 | 52 21·5 | 4 33 51 | |
| 7 | 54 3·2 | 4 29 51 | |
| 8 | 55 44·5 | 4 25 58 | 0·521 |
| 9 | 57 25·5 | 4 22 13 | |
| 10 | 18 59 6·0 | 4 18 33 | |
| 11 | 19 0 46·1 | −4 15 3 | |

During the week the comet moves slowly north-eastwards through the northern portions of Scutum Sobieski, and should be looked for in the early morning.

SECOND WASHINGTON STAR CATALOGUE.—Appendix I. to the Washington Observations of 1892 has recently been issued, and is devoted to the publication of the catalogue of standard stars which has been compiled from the work done with the transit circle of the U.S. Naval Observatory during the last thirty years. The instrument was made by Pistor and Martins, of Berlin, and was used almost continually from January 1866 to June 1891, being successively under the charge of Profs. Newcomb, Hall, Harkness, and Eastman. Prof. J. R. Eastman, who had the direction of it from 1874 to 1891, has had almost entire charge of the catalogue, and it is therefore issued in his name. Of the 72,914 observations embodied in the book, 17,334 were made by him personally and 39,867 under his immediate supervision.

The first half of the volume is occupied by descriptions of the apparatus and methods of reduction of the observations. Next come the tables of annual results; then a catalogue of stars employed in the American Ephemeris. The general catalogue, with which the book concludes, gives data for 5151 stars, all for the epoch 1875·0.

SPECTRA OF STARS OF CLASS III. *b*.—Prof. W. C. Dunér, of the Upsala Observatory, has been revising his survey of the red stars by means of the new Steinheil refractor, erected there in 1893. This has a visual objective of 36 cm. aperture, and a photographic objective of 33 cm. aperture. All the spectroscopic observations have been made with ocular spectroscopes of the Zöllner type, with dispersions varying from 3°·5 to 10° from C to G (*Astrophysical Journal*, vol. ix. p. 119, 1899).

In most cases, the previous results were confirmed, but in several of the brighter stars of this class he has found additional features. In all the brighter stars the band 5 (λ 576) is seen to be double, while near to the less refrangible edge of band 6 (λ 5636) a bright band is seen. Additional confirmation of the reality of these details is provided by the photograph of the spectrum of 132 Schjellerup in the *Astrophysical Journal*, vol. viii., which clearly shows a bright line at λ 5595. Variations in the relative intensities of the bands are common, notably in the case of bands 6 (λ 5636) and 4 (λ 586). In 152 Schj., the brightest of this class of stars, band 6 and 9 are very bright, while band 4 is quite faint. In 280 Schj. band 4 is the strongest in the spectrum, while band 6 is scarcely visible. Prof. Dunér thinks that, by a closer attention to these variations, a classification of these red stars would be rendered possible.

## LEAD COMPOUNDS IN POTTERY GLAZES.[1]

IT has been known for some months that Prof. T. E. Thorpe, F.R.S., and Prof. T. Oliver, had been commissioned by the Home Secretary to investigate the use of lead compounds in the production of pottery glazes and colours, and to suggest means which might be adopted to counteract the evils admitted, on all hands, to follow from their use. It had been found considerably easier by those who had drawn public attention to these evils even to exaggerate them, grave as they were, than to devise remedies which had any chance of practical adoption at the hands of the trade. The scientific eminence of Profs. Thorpe and Oliver, and their practical acquaintance with the details of many manufacturing processes, warranted the opinion that the choice of the Home Office was a wise one. The appearance of their report marks a very welcome stage in the treatment of this troublesome and intricate question. There exists in this country a pottery industry of considerable dimensions, producing pottery wares of infinite variety, and supplying, not merely the demands of our own country, but possessing, probably, a larger export trade than that of any similar industry in the world. This industry has been built up on the practical experience of generations of workers in the same business. The methods in use may appear, in many cases, to be the reverse of scientific; but, at all events, they have sufficed for the production of pottery of excellent make and finish, at a price which enables our potters still to hold their own, in spite of the efforts of their foreign rivals to copy their methods, their shapes, and their designs. It is idle for any one to deny the fact that, for pottery such as forms the bulk of our productions, glazes containing lead compounds are the simplest and the most trustworthy, and best fulfil all the requirements of a difficult and complicated manufacture. It is admitted, however, that lead compounds, used in the form and proportions common in English practice, may, and often do, cause serious illness and suffering—amounting in extreme cases to blindness, paralysis, and death—to those employed in certain of the processes of pottery production. Regulations have been framed from time to time by the Home Office, designed to minimise these evils. The latest proposals of this kind, which came into force only at the end of last year, deal with the removal of dust from work-rooms; the provision of means by which dust containing lead compounds shall be kept from the face of the worker; the provision of overalls and head coverings, as well as adequate and convenient washing accommodation for all workers who come in contact with lead compounds; and last, but by no means least, provide for a compulsory monthly medical examination of all women and young persons employed in certain specified occupations. These regulations, which are set out in full on pp. 43–45 of the report, are in startling contrast with the official regulations in force in foreign countries. While foreign Governments have for the most part either made

[1] Report to Her Majesty's principal Secretary of State for the Home Department on the employment of Compounds of Lead in the Manufacture of Pottery. By Prof. T. E. Thorpe, LL.D., F.R.S., and Prof. Thomas Oliver, M.D., F.R.C.P.

no regulations at all, or have confined themselves to benevolent advice (see report, pp. 46–50), we have in this country adopted, on the initiative of the Home Office, and with the assent of manufacturers, regulations on the points named above, which cannot fail to diminish the more serious evils complained of. Doubtless the pottery manufacturers will be grateful to Profs. Thorpe and Oliver for establishing this point.

It was felt, however, that important and valuable as such regulations may be, they leave untouched the kernel of the whole question. The terms of reference contained in the letter from the Home Secretary inviting the co-operation of Prof. Thorpe put the matter very clearly: The Secretary of State desires to ascertain (1) how far the dangers may be diminished or removed by substituting for the carbonate of lead, ordinarily used, either (*a*) one or other less soluble compounds of lead, *e.g.* a silicate; (*b*) "leadless" glaze; (2) how far any substitutes found to be harmless or less dangerous than the carbonate, lend themselves to the varied practical requirements of the manufacturer; (3) what other preventive measures can be adopted.

The report sets forth in a clear, simple, and decided form the conclusions arrived at on these points. It furnishes an account of visits paid to various pottery works on the continent. Results are given of the analytical determination of the proportion of lead compounds in glazes collected from a number of potteries in this country. Valuable tables are also given as to the solubility of various lead compounds, and of certain pottery "fritts" and glazes containing lead, in dilute, hydrochloric, and acetic acids; and, *inter alia*, we find that Prof. Thorpe has discovered in the course of his investigations a compound silicate containing 22 per cent. of lead oxide, which, he says, is insoluble in dilute acids. We are also furnished with the considerations and arguments on which the Professors have based their recommendations.

The recommendations themselves are four in number, and may be summarised as follows:—

(1) The prohibition of lead compounds entirely in the glazes used on seven-tenths of the wares produced in the potteries.

(2) That in all other branches of the pottery industry lead shall only be used in the form of a fritted compound silicate.

(3) That the use of raw lead—*i.e.* white lead—in glazes or colours should be absolutely prohibited.

(4) That the employment of women and young persons as dippers, dippers' assistants, ware cleaners after dippers, and glost placers should be prohibited in all factories where glazes containing lead continue to be used.

That these conclusions, if carried into effect, would do away with lead-poisoning in the pottery industry, there can be no two opinions. That the first and fourth of them, if insisted on in the present state of our knowledge, would cause, not only a serious dislocation of the pottery industry, but the transference of some of it to our foreign rivals (who are, for the most part, under no restrictions whatever as to their use of lead compounds or female labour), there can also be little doubt. Even in view of such circumstances, the adoption of these conclusions might be considered advisable, if an impartial consideration of the facts stated in the report showed that no other conclusions would meet the case. It is necessary, therefore, to consider whether the conclusions arrived at by Profs. Thorpe and Oliver are justified by the information given in the report. It may be said at once that a careful consideration of the report leads one to the conclusion that they are not.

The facts contained in the report may be summed up as follows:—

(1) English potters, generally speaking, use glazes containing "raw," *i.e.* "unfritted" white lead. This compound finds its way into the system, and being readily soluble in the gastric juice produces an excessive amount of lead-poisoning.

(2) Women and young persons are stated to be more susceptible to lead-poisoning in this way than adult males. The figures quoted are open to other interpretations.

(3) Leadless glazes are being tried by several manufacturers in this country on a limited scale. The results obtained so far may be described as satisfactory; but that they have been tried on an adequate scale, and under widely varying conditions, there is not sufficient evidence to prove.

(4) Certain foreign manufacturers, producing pottery similar to that produced in this country, have abandoned the use of "raw" white lead in their glazes.

(5) The glazes stated in the report to be used by these manufacturers contain as large a percentage of lead monoxide as is contained in the glazes used for similar purposes in this country.

(Compare table 1 on page 38 of the report, giving the percentages of lead monoxide found in certain earthenware glazes used in Staffordshire, with the percentages of lead oxide found in the foreign glazes, mentioned on pp. 16–25 of the report.)

(6) The lead compound used in these foreign glazes is either a bisilicate of lead ($PbO2SiO_2$), or a compound silicate containing as bases oxide of lead, alumina, lime, and alkalies (report, pp. 16–25).

(7) Wherever these compounds have been introduced in place of white lead, lead-poisoning has disappeared (report, see pp. 17, 18, 20, 25).

(8) The foreign manufacturers above mentioned use "leadless" glazes no more than English potters do.

(9) Women and young persons are employed at these factories as dippers, dippers' assistants, ware cleaners after dippers or glost placers, and yet there are no cases of lead-poisoning.

The statements thus briefly presented are an accurate summary of the information contained, on these points, in the report, and it is evident that they furnish no warrant for the first and fourth conclusions arrived at by Profs. Thorpe and Oliver. No one doubts that it would make assurance doubly sure to prohibit the use of lead in the glazes used on seven-tenths of the pottery produced in the "potteries" district of Staffordshire. The report contains very little evidence to show that such a cutting of the Gordonian knot is practicable, while it furnishes ample evidence that so drastic a regulation is not required to abolish "plumbism." English potters, from the time of Josiah Wedgwood down to the present, have made numberless experiments to produce leadless glazes. In a paper by Mr. W. P. Rix, published in the *Journal* of the Society of Arts of March 3, 1899, an account is given of the best known of these, and it is shown clearly that in almost every case their use has been abandoned, in some cases after a very lengthy trial, because of practical difficulties connected with their production, which made them too uncertain for general use. The experiments to which Profs. Thorpe and Oliver refer on p. 9 of their report are too recent and too incomplete to afford any justification for the sweeping statement made on that page in the following words, the italics being mine:—

"We have no doubt whatever that leadless glazes, of sufficient brilliancy, *covering power*, and durability, and adapted to all kinds of table, domestic, and sanitary ware, are now within the reach of the manufacturer."

As a matter of fact, it is known to every practical potter who has experimented with leadless glazes, and to none better than those who are working with them at the present time, that leadless glazes of sufficient stability—*i.e.* containing a sufficiently high percentage of alumina to bring them into agreement with the ware—do not become fluid (or "flow," as the potter calls it) in the firing to the same extent that lead glazes do. They are, consequently, deficient in that "covering power," as a potter understands the term, that Profs. Thorpe and Oliver claim for them.

At the general firing temperature of English earthenware glazes, a leadless glaze, even of the very latest type, becomes clear and glossy, but it does not become fluid. It follows from this, that the slightest inequality of thickness produced in the dipping remains after firing; that any small bit knocked or chipped out of the glaze coating before it is fired—an accident of the most ordinary occurrence—leaves a bare spot, for the glaze cannot flow over the space as a lead glaze would; moreover, the mending of imperfectly glazed pieces before firing is rendered almost impossible for the same reason. These points are of the utmost importance in practice, for, while greater care must be taken in sorting the bisque ware before dipping, as well as in the operations of dipping and placing, the proportion of defective pieces may still be too great to be borne. That, at all events, is the past experience of the potters who have worked with leadless glazes; and I feel assured that no firm of pottery manufacturers in this country is prepared to abandon leaded glazes for all their ordinary earthenware at the present time, and face the consequences. I cannot but consider that in this matter Profs. Thorpe and Oliver have been misled by the natural enthusiasm of those who have recently produced leadless glazes, and in their desire to put an end to the evils of lead-poisoning they have over-stated the

present value of leadless glazes to the trade at large. The time is not yet ripe for the drastic change proposed in their first recommendation.

Their third conclusion, "that the use of 'raw' lead, *i.e.* 'unfritted' lead, as an ingredient of potters' glazes or colours, should be absolutely prohibited," is not one whit too strong. The experience of pottery manufacturers in this country and on the continent proves that such a course is possible in every section of the trade. Between the bisilicate of lead containing 65 per cent. of lead monoxide, used at Rörstrand (report, p. 20) and at Dresden (report, p. 25), and proved in the experience of those works to have abolished lead-poisoning, and the compound silicate discovered by Prof. Thorpe (see report, p. 32) containing 22 per cent. of lead-oxide, and stated to be insoluble in dilute acids, and therefore non-injurious, there would seem to be ample margin for all the potter's requirements. According to the evidence contained in the report, such compounds have been used for years, or might be used, without producing lead poisoning in those who work with them. Were the use of such of these compounds as are found to best answer the practical requirements of the various trades, made compulsory on every potter in this country, and the Factory Inspectors empowered to take samples from the dipping-tubs for examination in the Government Laboratory, the axe would indeed be laid to the root of this evil.

The report is to be commended to the careful consideration of every one interested in a great industry. The facts stated in it, speaking generally, admit of little or no dispute. From a careful consideration of its pages, one gathers the encouraging conviction that it contains information which will enable the question to be fairly and satisfactorily dealt with from the point of view of workman, manufacturer, and Home Office alike. Its second and third recommendations, worked in conjunction with the monthly medical examination of *all* workers, of whatever sex or age, who come in contact with any form of lead compound, and with the adequate protective provisions as regards ventilation, clothing, and cleanliness, now in force at all pottery works in this country, would put an end, within a reasonable time, to the gross evils of plumbism. It is to be hoped that the pottery manufacturers will rise to the situation, and show their willingness to adopt such of the recommendations contained in the report as are of practical value.[1] The existing state of things, at all events, cannot be allowed to continue.

W. BURTON.

## *MECHANICAL ENGINEERING IN WARSHIPS.*

THE address delivered at the Institution of Mechanical Engineers on Thursday last, by the President, Sir William H. White, K.C.B., F.R.S., was a valuable statement of the part which mechanical engineering has played in the growth of our shipbuilding industry and the development of our mercantile marine during the past forty years. Mechanical engineering has intimate relations with all other branches of engineering, but with none has it been more closely associated than with shipbuilding in recent times; and in his address Sir William White indicated the directions in which the construction and working of ships have been influenced by it. He showed how the development of mechanical appliances for the equipment and working of ships during the last forty years is no less remarkable than the advance in the machinery used for shipbuilding. Nearly all steamships are now fitted with mechanical steering gear, mostly steam, in some instances hydraulic, and in a few recent ships electrical. The same motive powers are now used for working anchors and cables in steamships. Artificial ventilation is now very largely employed in many classes of ships, and especially in warships; electric lighting is becoming the rule; mechanical power is universally employed for pumping purposes in steamships; remarkable progress has been made in appliances for lifting coal and cargoes; and refrigerating machinery has led to the development of a new branch of the shipping industry, as well as added to the health and comfort of all who travel by sea. The advances in these and other directions were sketched by Sir William White, but the limitations of space prevent the publication of his address in full. The last section dealt with mechanical engineering in warships, and is here reprinted.

[1] The pottery manufacturers have already taken action in the direction indicated.

### *Mechanical Engineering in Warships.*

The auxiliary machinery of warships necessarily has much in common with the corresponding machinery in merchant ships. There are, however, many special requirements arising from their armament and equipment as fighting machines, and hence it happens that in warships the applications of mechanical power reach their fullest development. Modern warships are sometimes styled "boxes of machinery," and the description is not inapt. The tendency is, in fact, to multiply machines, and to minimise manual labour to an extent which is not universally approved. On the other hand, with modern armaments and equipment, an extensive use of mechanical power is inevitable, and the expenditure of fuel on auxiliary services grows greater in proportion to that devoted to propulsion.

Ten years ago in a first-class battleship of 12,000 h.p. (maximum) for the propelling machinery, there were fifty auxiliary engines capable of indicating in the aggregate about 5000 h.p. if they all worked simultaneously—which they did not, of course. To-day, a similar statement would show a growth in the auxiliary power as compared with the propelling.

The multiplication of auxiliary services makes very serious demands upon the coal-supply of warships. Even in harbour the expenditure of coal is large on lighting, distilling, ventilation, air-compression, drilling with the heavy guns, and other services. From 10 to 25 tons a day may thus be expended in a large battleship or cruiser of high speed. As warships cruise at low speeds and spend much time in harbour, it results that, taking the year through, fully as much coal is burnt for auxiliary services as for propulsion. Coal endurance being one of the most important factors in warship efficiency, facts such as these have tended to cause a doubt as to the wisdom of more widely extending mechanical appliances. It is pointed out that manual power with simple fittings, such as can be readily replaced if damaged in action, can compete with mechanical appliances in many directions; and that it is better to have larger crews in fighting ships, so as to provide a margin for inevitable casualties, than to use the alternative of labour-saving machines liable to derangement or injury and not easily repaired in action. The practical solution of the problem clearly lies in the due proportion being found between manual and mechanical appliances.

Gun construction in its modern form is largely dependent upon mechanical engineering. Your past-Presidents, Lord Armstrong and the late Sir Joseph Whitworth, were famous as mechanical engineers before they undertook the design and manufacture of guns. In this Address, however, the story of progress from the smooth-bore cast-iron 68-pr., weighing 95 cwts., to the 110-ton breech-loading rifled gun, firing 1800-lb. projectiles, can find no place. Nor can more than a brief glance be taken at the interesting work done by the mechanical engineer in regard to appliances for mounting, working, and loading modern guns, supplying the ammunition, and securing rapidity and accuracy of fire with a minimum of labour.

Anyone who will study the breech mechanism and mounting of a hand-worked quick-firing gun will discover a triumph of mechanical engineering over a very special and difficult problem. Take, for example, a 6-inch quick-firing gun of the latest naval pattern. The gun weighs about 7 tons, fires 100-lb. projectiles, with a muzzle velocity of nearly 2800 feet per second, and an energy of 5370 foot-tons, corresponding to a penetration of 22 inches of wrought iron. Its breech mechanism is so devised that four or five aimed shots can be fired per minute. Its mounting is so arranged that the gun can be easily trained, elevated or depressed by one man. The great energy of recoil is perfectly controlled, and the crew numbers only four or five men. If such a gun is compared with the 68-pr. smooth-bore muzzle loader, mounted on a wood truck carriage with rude arrangements for elevating, and still ruder for training and controlling recoil, one has a striking illustration of the progress made in forty years with hand-worked guns.

When one passes to heavier guns worked by mechanical power, a still greater contrast appears. The 110-ton gun of 16¼ inches calibre has charges of 960 lbs. of powder and 1800-lb. projectiles. Fired with a velocity of 2100 feet per second, three projectiles have an energy of 54,000 foot-tons with an estimated penetration of 37 inches of wrought iron. Obviously, manual power alone was unequal to working such guns. The mechanical engineer has devised suitable machinery which enables pairs of guns, mounted in a thickly armoured turret, to be

loaded, trained, elevated, and depressed with ease and comparative rapidity under the guidance of a few men. Mr. George Rendel was one of the first, as well as one of the most successful, workers in the design of mechanical appliances for working heavy guns by hydraulic power. Messrs. Armstrong have from the first taken a leading position in this class of work. Messrs. Whitworth, and, in more recent times, Messrs. Vickers, have also undertaken it on a large scale. Hydraulic power finds most favour in the Royal Navy. Abroad, electrical power is now extensively used. Pneumatic power has been employed in a few cases.

Improvements in gun-design and in explosives have resulted in an increased ratio of power to weight in the latest types of guns. As a result, in the latest completed battleships, guns of 12-inch calibre, weighing 46 tons, firing 850-lb. projectiles, with muzzle velocities of about 2400 feet per second, and energies of 33,000 foot-tons have been used instead of the 67-ton and 110-ton guns of early date. These reduced weights of charges and projectiles are more easily handled; and this fact, together with certain changes in the system of mounting, have enabled many of the operations of loading and working the guns to be performed by manual power as well as by hydraulic power. This duplication is obviously advantageous, and reduces greatly the risk of heavy guns being put out of action. There was a time when a return to guns of still smaller dimensions, capable of being worked exclusively by hand-power, was strongly advocated. It was urged that it was unwise to depend at all on mechanical power, because it might fail at a critical moment. Such arguments are now but little heard. Experience does not demonstrate that any serious risk of "breakdown" need be feared in mechanical appliances. Moreover, the advocates of manual power overlooked the fact that, supposing that system had been adopted, there must still remain in all modern mountings and breech mechanisms many comparatively delicate parts, perhaps more liable to injury or derangement than the appliances which were condemned.

Steady improvement has been made in heavy gun mountings and in rapidity of fire. For example, with 12-inch guns from two and a half to three minutes were formerly considered to be a reasonable interval between successive rounds; now that interval has been brought below one minute, when pairs of guns are loaded and fired. Loading has also been made possible with the guns in any position, whereas formerly the guns were brought to fixed hoists, and to a definite angle of elevation for loading. It is most interesting to watch the working of these heavy guns, by means of mechanisms controlled by a few men. All the operations are performed with rapidity and precision, from the moment projectiles and charges are moved from their stowing positions in shell rooms and magazines situated deep down in the holds, up to the time when they are rammed home in the gun, the breech closed and the gun made ready for firing. Then one sees the captain of the barbette or turret training or changing the elevation of the gun up to the instant when he fires by electricity, and the huge projectile is discharged.

Passing from guns to torpedoes, one finds a fresh example of the important work done by mechanical engineers. The inventor of the automobile torpedo, Mr. Whitehead, is an eminent member of the profession. The torpedo itself is a beautiful example of mechanical engineering. All the machinery connected with air compression and storage, all the arrangements for ejecting above or below water, involve skilful mechanical design. Nor is this all. From the introduction of the torpedo has sprung the necessity for special structural and defensive arrangements in warships, as well as the construction of the swift torpedo flotilla-boats, destroyers, gunboats and depot ships, whose performances are not merely remarkable, but suggestive of possibilities in regard to steam navigation at high speeds.

The smaller classes of boats using the locomotive torpedo have to be carried by warships. They weigh, fully equipped, 18 to 20 tons, or about three times as much as the heaviest load ordinarily dealt with in merchant ships by their own lifting gear. This has involved the design of special lifting appliances for warships. After long experience in the Royal Navy, the most suitable arrangement has been found to be a strong steel derrick carried by the mast, with powerful steam or hydraulic hoists working tackles which lift the boats and top the derrick. Winches or capstans are also used in some instances for swinging the derricks. Admiralty specifications require that the lifting gear shall be capable of dealing with a load of about 18 tons lifted by a single wire rope, as well as with a load of 9 tons raised 30 feet per minute. In one ship, the *Vulcan*, built as a torpedo depot ship and boat carrier, instead of derricks two powerful hydraulic cranes are fitted. She carries six steel torpedo boats, 60 feet long and of 16 knots speed, besides sixteen other boats, some of large size. The total weight of these boats is 150 tons, and they are placed 27 feet above water. The two cranes and their gear weigh 140 tons; the tops of the cranes are 55 feet above water. It required careful designing to meet such exceptional conditions satisfactorily and to produce a stable and seaworthy ship. She has now been many years on service and has a good reputation.

Besides these special boat-lifting appliances, warships commonly have special coal-hoists, transporters and other gear for the purpose of accelerating the taking of coal on board. Rapidity in coaling must be of great importance in time of war, and keen competition between ships in the various squadrons as to the rates attained have led to great improvements in details of gear, as well as to remarkably rapid coaling becoming the rule in the Royal Navy. Recently, at Gibraltar, the *Majestic* took on board 1070 tons of coal in 6 hours and 10 minutes—a very fine performance.

All the larger ships in the Royal Navy have engineers' workshops fitted with a considerable number of machine-tools, driven by power, and of sufficient size to deal with ordinary repairs. The *Vulcan* is a special vessel in this sense also, as she has an exceptionally well-equipped workshop, a small foundry and a hydraulic press for forgings. For repairs of the boats she carries, or for those of torpedo boats and destroyers in company, or for certain repairs to ships of the fleet to which she is attached, the *Vulcan* has been found most useful. Besides being a floating factory and a boat carrier, she has a large torpedo and mining equipment, an electrical laboratory, and serves as a school of instruction for mining and torpedo work. In addition, she is a swift cruiser, with a fair armament and well protected. As an armed ship, she represents the fullest application of mechanical appliances afloat. Her construction was commenced in 1887. Other navies have since imitated her.

Another *Vulcan* was fitted up as a floating factory to serve with the American fleet during the recent war. She was originally a merchant steamer, but is said to have proved of great service. Naval opinion seems to favour the use of vessels of this class with fleets. It is held, moreover, that no modern fleet can be considered to be complete unless the fighting ships are supplemented by ships specially equipped for distilling and storing fresh water, or carrying coals, ammunition and reserve stores.

## SATURN'S NEW SATELLITE.

IN *Harvard College Observatory Circular*, No. 43, just received, Prof. E. C. Pickering gives the following detailed account of the discovery and observations of the new satellite of Saturn:—

Nearly all of the astronomical discoveries made by the aid of photography have related to the fixed stars. In the study of the members of the solar system, the results obtained by the eye are generally better than those derived from a photograph. For many years it has been supposed that photography might be used for the discovery of new satellites, and in April 1888 a careful study of the vicinity of the outer planets was made by Prof. William H. Pickering. Photographs were taken with the 13-inch Boyden telescope, with exposures of about one hour, and images were obtained of all the satellites of Saturn then known except Mimas, whose light is obscured by that of its primary. It was then shown that Saturn probably had no satellite, as yet undiscovered, revolving in an orbit outside of that of Enceladus, unless it was more than a magnitude fainter than Hyperion (Forty-third Report Harv. Coll. Obs., p. 8).

In planning the Bruce photographic telescope, a search for distant and faint satellites was regarded as an important part of its work, and accordingly plates for this purpose were taken at Arequipa by Dr. Stewart. A careful examination of these plates has been made by Prof. William H. Pickering, and by superposing two of them, A 3228 and A 3233, taken August 16 and 18, 1898, with exposures of 120 m., a faint object was found which appeared in different positions on the two plates. The same object is shown on two other plates A 3227 and A 3230, taken

on August 16 and 17, 1898, with exposures of 60m. and 122m. respectively.

The position is nearly the same on the two plates taken on August 16, but on August 17 it followed this position 33″, and was south 19′, while on August 18 it followed 72′, south 43″. Its motion was direct, and less than that of Saturn, though nearly in the same direction. It cannot, therefore, be an asteroid, but must either be a satellite of Saturn or a more distant outside planet. The proximity of Saturn renders the first supposition much more probable. On August 17 the position angle from Saturn was 106°, and the distance 1480″. Assuming that it was at elongation, and that its orbit is circular, its period would be 400 days, or five times that of Japetus. It was at first identified with a very faint object found on plates taken in 1897, and the period of seventeen months was derived from them. This supposition has not been confirmed.

Measurements of the positions of the images give additional material for determining the form of the orbit. The method of measurement is that described in the *Annals*, vol. xxvi. p. 236. The uncorrected positions of the four images referred to the first plate of August 16 as an origin, are for $x$, 0″·0, +1″·2, +33″·6, and +71″·8; for $y$, 0″·0, −1″·7, −19″·8, and −42″·1; the corresponding Greenwich mean times are 12h. 16m., 14h. 18m., 12h. 56m., and 13h. 12m. Correcting for the motion of Saturn, the relative motion with reference to that body is in $x$, 0″·0, −2″·4, −10″·7, and −22″·0; in $y$, 0″·0, +0″·1, +2″·4, and +2″·9. It appears from this that the apparent motion is about 10″·4 a day, at a distance of 1480″. A computation shows that if the orbit is circular, the period must be either 4200 or 490 days, according as the satellite is near conjunction or elongation. These values may be greatly altered if the orbit is elliptical. Since the interval of time between the first and last photographs on which the satellite appears is only two days, it is impossible to predict its position with accuracy. It is probable that its position angle from Saturn now lies between 280° and 290°, and its distance between 20′ and 30′. These uncertainties will probably be greatly diminished from measures of plates of Saturn taken in Arequipa on September 15, 16, and 17, 1898, which for some unexplained reason have not yet been received in Cambridge.

The direction of the motion, which is nearly towards Saturn, shows that the apparent orbit is a very elongated ellipse, and that it lies nearly in the plane of the ecliptic. Prof. Asaph Hall has pointed out that this is to be expected in a body so distant from Saturn. The attraction of the latter only slightly exceeds that of the sun. Hyperion appears as a conspicuous object on all four of the plates, and the new satellite appears about a magnitude and a half fainter on each. The approximate magnitude is therefore about 15·5. As seen from Saturn, it would appear as a faint star of about the sixth magnitude. Assuming that its reflecting power is the same as that of Titan, its diameter would be about two hundred miles. It will, therefore, be noticed that while it is probably the faintest body yet found in the solar system, it is also the largest discovered since the inner satellites of Uranus in 1851. The last discovery of a satellite of Saturn was made in September 1848 by Prof. William C. Bond, then director of this Observatory, and his son, Prof. George P. Bond. The satellite Hyperion was seen by the son on September 16 and 18, but its true character was first recognised on September 19, when its position was measured by both father and son (see *Annals*, ii. p. 12). Soon afterwards it was discovered independently by Lassell, at Liverpool.

Prof. William H. Pickering, as the discoverer, suggests that the name Phœbe, a sister of Saturn, be given to the new satellite. Three of the satellites—Tethys, Dione, and Rhea—have already been named for Saturn's sisters, and two, Hyperion and Japetus, for his brothers.

## *UNIVERSITY AND EDUCATIONAL INTELLIGENCE.*

Cambridge.—The following are the speeches delivered on April 27 by the Public Orator, Dr. Sandys, in presenting (1) Prof. Sir William Turner and (2) the Rev. Prof. Wiltshire, for the honorary degree of Doctor in Science:—

(1) Virum regni totius medicorum concilio praepositum, virum honoribus academicis plurimis cumulatum, etiam noster Senatus titulo suo decorare anno proximo decrevit. Inter Lancastrienses natus, inter Londinienses educatus, inter Edinenses, medicinae in schola celeberrima, quam tot coloniae Britannicae studiorum medicorum quasi μητρόπολιν venerantur, anatomiae scientiam per annos plus quam triginta praeclare professus, non modo Universitati suae aedificiis novis instruendae operam insignem dedit, sed etiam studiorum suorum actis per seriem edendis iamdudum maxima cum laude praefuit. Idem, rerum naturae spoliis olim in Britanniam feliciter reportatis, Australasiae praesertim anthropologiam opere in magno accuratissime expositam luculenter illustravit. Nuper societatis Britannicae scientiarum finibus proferendis praeses in annum proximum designatus, ab eadem disputationibus de anthropologiae scientia etiam inter Canadenses habendis haud ita pridem praepositus, hominum omnium plausus propterea praesertim meritus est, quod simiarum superbiam recentem repressit et generis humani dignitatem veterem denuo vindicavit.

Duco ad vos generis humani vindicem, equitem insignem, anatomiae professorem illustrem, Willelmum Turner.

(2) Unus ex alumnis nostris, societatis geologicae, astronomicae, Linnaeanae socius, idcirco praesertim inter peritos laudatur, quod palaeontographicae societatis in usum, palaeontologiae studiosorum ad fructum, aevi prioris monumenta a rerum natura in saxis impressa, non sine summo ingenio et labore illustrata, per annos plurimos litterarum monumentis mandaverit. Idem Universitatem nostram beneficio singulari ad sese devinxit, quod non modo bibliothecam suam, sed etiam vitae antiquae relliquias veteres in saxis conservatas et saxorum inter se diversorum exempla quam plurima, nuper nobis in perpetuum donavit. Illa vero exempla omnia, olim inter Londinienses in Collegio Regali professor, docendi praesertim in commodum collegerat, cum Horatio (ut videtur) arbitratus "demissa per aurem quam quae sunt oculis subiecta" animum segnius excitare. Etiam ipsa fama liberalitatis tantae nuper inter nosmet ipsos inter rerum naturae praesertim studiosos animum gratum excitavit. Quanto magis iuvat Universitatem totam liberalitatis tantae auctorem ipsum hodie oculis suis redditum et auspiciis optimis praesentem contemplari. Qui prioris aevi tot exempla nobis donavit, ipse nostro in saeculo munificentiae in Universitatem nostram ab aliis imitandum praebuit exemplum.

Praesento vobis geologiae professorem emeritum, virum de rerum naturae studiis praeclare meritum, Thomam Wiltshire.

Prof. A. Cornu, of the École Polytechnique of Paris, has been appointed Rede Lecturer for the present year. The lecture will be delivered in the Senate House on June 1, as a part of the proceedings relating to the jubilee of Sir G. G. Stokes. On the same evening, a conversazione will be held in the Fitzwilliam Museum. Next day an address from the University and a commemorative gold medal will be presented to the veteran Lucasian professor. The guests of the University will be received by the Chancellor, and certain honorary degrees will be conferred. A garden-party at Pembroke College, and a State dinner in the evening, will close the festivities.

Prof. Macalister announces three lectures of an historical character, on eponymous structures in human anatomy, on May 9, 13, and 16.

University tables are vacant at the Naples and the Plymouth Zoological Stations. Applications are to be sent to Prof. Newton by June 1.

The *Times* makes the following announcement:—"We understand that Mr. Passmore Edwards has intimated his intention of giving 10,000*l*. upon trust to equip a school and building for the teaching of economics and commercial science in the New London University. The Trustees, who are to carry out the trust and offer the building when ready to the new University Senate, are the Bishop of London, Mr. Sidney Webb, and Mr. Haldane, Q.C., M.P. The work of the London School of Economics will probably be continued there. Further endowments will, of course, be wanted for chairs of banking, commercial history and geography, commercial law, insurance and other special subjects, and this munificent gift by Mr. Passmore Edwards should encourage other wealthy Londoners to imitate his generosity."

## SOCIETIES AND ACADEMIES.

### LONDON.

**Royal Society**, April 20.—"On Intestinal Absorption, especially on the Absorption of Serum, Peptone, and Glucose." By E. Waymouth Reid, F.R.S., Professor of Physiology in University College, Dundee, St. Andrews University, N.B.

The experiments detailed in the full paper deal with the absorption from the intestine, of the animal's own serum, and of solutions of glucose and peptone. The method employed has been that introduced by Leubuscher, in which two loops of intestine are simultaneously employed, the one the experimental, and the other the control, loop.

The conclusions arrived at are as follows :—

(1) A physiological activity of the intestinal epithelium in the act of absorption is demonstrated by—

(*a*) The absorption by an animal of its own serum (or even plasma) under conditions in which filtration into blood capillaries or lacteals, osmosis and adsorption are excluded.

(*b*) By the cessation or diminution of the absorption of serum when the epithelium is removed, injured or poisoned, in spite of the fact that removal, at any rate, must increase the facilities for osmosis and filtration.

(2) The activity of the cells is characterised by a slower uptake of the organic solids of the serum than of the water, and a rather quicker uptake of the salts than of the water. The relations to one another of the absorptions of these various constituents is variable in different regions of the intestinal canal (upper ileum, lower ileum, and colon).

(3) No evidence can be obtained of specific absorptive fibres in the mesenteric nerves.

(4) The state of nutrition of the cells is the main factor in their activity, and this is intimately associated with the blood supply.

(5) In reduction of the rate of absorption, without detachment of epithelium, the absorption of the various constituents of serum is reduced in the proportion in which they exist in the original fluid.

(6) The activity of the cells may be raised by stimulation with weak alcohol, without evidence of concomitant increase of blood supply.

(7) The bile has no stimulant action on the cells.

(8) The cells exhibit an orienting action upon salts in solution (sodic chloride especially). In a loop of gut with injured cells, sodic chloride enters the lumen from the blood at a time when it is being actively absorbed from a normal control loop in the same animal. (This fact was first noted by O. Cohnheim.)

(9) The absorption of water from solutions introduced into the gut is dependent upon two factors :—

(*a*) The physical relation of the osmotic pressure of the solution in the gut to the osmotic pressure of the blood plasma.

(*b*) The physiological regulation of the difference of osmotic pressure by the orienting mechanism of the cells.

(10) The chief factor in the absorption of peptone is an assimilation (or adsorption) by the cells, while in the absorption of glucose, diffusion, variable by the permeability of the cells (and so, probably, related to their physiological condition) is the main factor.

(11) By removal of the epithelium, the normal ratio of peptone to glucose absorption is upset, and the value tends to approach that of diffusion of these substances through parchment paper into serum.

(12) Absorption in the lower ileum is greater for the organic solids of serum, and less for peptone and glucose than in the upper ileum. The relative absorption of water in the upper and lower ileum is variable.

(13) The relative impermeability of the lower ileum to glucose disappears with removal of the epithelium.

(14) Absorption in the colon is for all constituents of serum, and for peptone and glucose far less per unit of measured surface than in the middle region of the ileum.

(15) The normal relative excess of salt absorption from serum over water absorption, observed throughout the intestine, is most marked in the colon, and more marked in the lower than in the upper ileum.

(16) Finally, it is suggested that the cell activity which causes serum to pass over to the blood is of the same nature as that involved in the orienting action of the cells upon salts in solution.

**Zoological Society**, April 18.—Prof. G. B. Howes, F.R.S., Vice-President, in the chair.—Mr. C. W. Andrews read a paper on the osteology of one of the great extinct birds of Patagonia, *Phororhacos inflatus*. He described in detail the structure of the skull and skeleton, and compared them with various recent forms of birds. The evidence as to the affinity of this type was somewhat conflicting, but on the whole pointed to a relationship with the *Gruiformes*, as had been previously suggested by the author. It seemed probable that the aberrent *Cariama* was the nearest living representative of *Phororhacos*, being related to it somewhat in the same fashion as the small modern Armadillos are to the great extinct forms such as *Glyptodon* and *Panochthus*.—A communication was read from Mr. P. W. Bassett-Smith, entitled "A systematic description of the parasitic Copepoda found on fishes." It contained a summary of the literature on the subject, and an enumeration of the known species of these parasites and lists of their synonyms. A new family (*Philichthydidae*) was introduced, to embrace the forms which are found in the mucous canals and sinuses of fishes, and a new genus (*Oralien*) was proposed for the reception of *Chondracanthus triglae* (Blainv.).—Mr. W. E. de Winton read a paper on the African species of *Canidae*. The author, from an examination of a series of specimens lately received from Africa, had come to the conclusion that the known species of *Canidae* of that continent were fourteen in number. He pointed out that the numerous supposed new species of jackals that had recently been described were mostly varieties of well-known forms, and that he was of opinion that only four species of jackals were found in Africa, viz. *Canis anthus*, *C. variegatus*, *C. mesomelas*, and *C. adustus*.—A communication from Dr. H. von Ihering, on the Ornis of the State of São Paulo, Brazil, was read. It embraced the conclusions arrived at, from observations made by the author during the last six years, regarding the distribution of birds in that State, in which he recognised elements of three different faunas—namely, the northern and southern divisions of the South-east Brazilian fauna, and the Central Brazilian or Pampas fauna of the interior.—A communication from Mr. G. A. Boulenger, F.R.S., contained the description of a new lizard from Ecuador under the name *Ameiva leucostigma*.—A communication was read from the Rev. O. Pickard-Cambridge containing descriptions of twelve new species of exotic Araneidea.

### MANCHESTER.

**Literary and Philosophical Society**, April 11.—Mr. J. Cosmo Melvill, President, in the chair.—Mr. John Watson read a paper entitled "On *Calinaga*, the single genus of an aberrant sub-family of butterflies." He first referred to the species known to science, and to the uncertainty as to where this curious butterfly should be placed in the classification of insects. It was pointed out that, besides the evidence of its geographical distribution, the structure of the feet pointed to the probability of its being a very ancient form. The basal cell shows a close affinity to the *Glacialis* section of *Parnassius*, and the general tendency of the structure of *Calinaga* was towards its being an offshoot—an early offshoot—of the Lepidopterous phylum from which the Papilioni-Pieri-Nymphalid stock originated. A paper on a biological aspect of cancer was read by Mr. F. J. Faraday. Cancer has been defined as epithelial proliferation, with an invading tendency. The author suggested that it was a case of arrested development, at what might be termed the cryptogamic as distinct from the phanerogamic stage. He pointed out that changes in the environment, noticeably a deficient supply of free oxygen and sunlight, had a remarkable influence in arresting organised differentiation and favouring the development of cryptogamic parasitism; and cited the attenuation and fermentation experiments of Pasteur and his successors. The "travelling cell" in cancer could only be described as a pathogenic micro-coccus evolved from normal epithelial cells. From analogy, the author inferred that deficient oxygenation of the blood generally, or deficient local blood-irrigation through local causes or interruptious, might account for the cancerous proliferation.

### PARIS.

**Academy of Sciences**, April 24.—M. van Tieghem in the chair.—The President announced to the Academy the death of M. Charles Friedel.—On surfaces of constant positive curvature, by M. Gaston Darboux.—Electrical registration of the valvular movements which determine the opening and closing of the orifices of the heart, by M. A. Chauveau. Diagrams obtained

by the apparatus are given, showing the curves of the tricuspid, mitral and aortic valves.—New observations of the planet EL (Coggia, March 31, 1899), made at the Observatory of Marseilles with the 26 cm. equatorial, by M. E. Stéphan.—Observations of the new Coggia planet (EL), made at the Observatory of Algiers with the 31·6 cm. equatorial, by M. Rambaud.—On the sterilisation of potable waters by ozone on the industrial scale, by MM. Marmier and Abraham. The apparatus was set up at Lille. After the water had passed through the ozonising column, all saprophytic and pathogenic organisms were destroyed with the exception of some spores of *Bacillus subtilis*; this organism also offering considerable resistance to all the usual methods of sterilisation.—On furfuryl alcohol, by M. G. André. Specimens of this alcohol prepared by different methods for calorimetric determinations differed considerably in purity, the method of Wissel and Tollens being the only one yielding a pure substance.—Osazones from oxycelluloses, by M. Léo Vignon. Cotton wool was oxidised in various ways to oxycelluloses, and these heated with phenylhydrazine in acetic acid solution. The osazones formed were not constant in composition.—On the sugar of maize stems, by MM. C. Istrati and G. Œttinger. Measurements of the reducing power before and after inversion of the juice from the stems of sixteen varieties of maize.—Remarks on a preceding communication "On the pathogenic agent of hydrophobia," by M. E. Puscariu. The amylaceous formations observed in the central nervous system of animals who died from hydrophobia have been found in cases of general paralysis, abscess of the brain and in diphtheric paralysis. Hence the view previously put forward, that these formations are of parasitic origin and peculiar to hydrophobia, is erroneous.—On the reducing power of the tissues: the blood, by M. Henri Hélier.—On a ratio existing between intraorganic oxidations and the production of kinetic energy in the organism, by M. Alexandre Poehl.—The microbes of flowers, by M. Domingos Freire. Numerous species of organisms have been found in flowers, including the pathogenic *Bacillus pyocyaneus*.—On the wines obtained by the preliminary heating of the vintage, by M. A. Rosenstiehl. The preliminary sterilisation of the must by heating and the subsequent introduction of suitable yeasts, in all the instances tried, gave a wine superior to that obtained by the traditional methods.—The specific characters of the fungus of *Pityriasis versicolor*, by M. Paul Vuillemin.—Researches on the mineral elements, especially iron, in the human fœtus, by M. L. Hugounenq.—The formation of the egg in *Myriothela* and *Tubularia*, by M. Alphonse Labbé.—Tangential increase of the pericycle, by M. Henri Devaux.—Discussion of barometric observations, by M. A. Poincaré.

## DIARY OF SOCIETIES.

*THURSDAY*, MAY 4.

ROYAL SOCIETY, at 4.30.—On the Chemical Classification of the Stars: Sir Norman Lockyer, F.R.S.—Demonstration of Vermiform Nuclei in the Fertilised Embryo Sac of *Lilium martagon*: Miss E. Sargant.—*Onygena equina* (Willd.): a Horn-destroying Fungus: Prof. Marshall Ward, F.R.S.—Impact with a Liquid Surface studied by the Aid of Instantaneous Photography. Paper II.: Prof. Worthington, F.R.S., and R. C. Cole.—The External Features in the Development of *Lepidosiren paradoxa* (Fitz.): J. G. Kerr.—An Observation on Inheritance in Parthenogenesis: Dr. E. Warren.—The Thermal Expansion of Pure Nickel and Cobalt: A. E. Tutton.

LINNEAN SOCIETY, at 8.—The Position of Anomalurus as indicated by its Myology: F. G. Parsons.—On *Notheia anomala*, Harv. et Bail.: Miss Ethel S. Barton.—On Variation in the Desmidiæ: G. S. West.

CHEMICAL SOCIETY, at 8.—On the Combustion of Carbon Disulphide: H. B. Dixon and F. J. Russell.—The Action of Nitric Oxide on Nitrogen Peroxide: H. B. Dixon and J. D. Peterkin.—On the Mode of Burning of Carbon: H. B. Dixon.—Crystalline Glycollic Aldehyde: Henry J. Horstman Fenton and Henry Jackson.—On the Blue Salt of Fehling's Solution and other Cupro-tartrates: Orme Masson and B. D. Steele.—The Preparation of Acid Phenolic Salts of Dibasic Acids: Dr. S. B. Schryver.—The Maximum Pressure of Naphthalene Vapour: R. W. Allen.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Electric Locomotives in Practice and Tractive Resistance in Tunnels, with Notes on Electric Locomotive Design: G. V. McMahon.

*FRIDAY*, MAY 5.

ROYAL INSTITUTION, at 9.—Pictures produced on Photographic Plates in the Dark: Dr. W. J. Russell, F.R.S.

GEOLOGISTS' ASSOCIATION, at 8.—The Drainage of Cuestas: Prof. W. M. Davis.

*SATURDAY*, MAY 6.

GEOLOGISTS' ASSOCIATION.—Excursion to the Thame District. Director: A. M. Davies. Leave Paddington at 9.50.

*MONDAY*, MAY 8.

SOCIETY OF ARTS, at 8.—Leather Manufacture: Prof. H. R. Proctor.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Explorations in the Bolivian Andes: Sir Martin Conway.

*TUESDAY*, MAY 9.

ROYAL INSTITUTION, at 3.—Electric Eddy-Currents: Prof. S. P. Thompson, F.R.S.

ANTHROPOLOGICAL INSTITUTE, at 8.30.—Ethnographical Notes on the Fang: Dr. Albert L. Bennett.

ROYAL PHOTOGRAPHIC SOCIETY, at 8.—The Photography of Colour: E. Sanger Shepherd.

*WEDNESDAY*, MAY 10.

SOCIETY OF ARTS, at 8.—Fruit-Growing in Kent: George Bunyard.

GEOLOGICAL SOCIETY, at 8.—The Geology of the Davos District: A. Vaughan Jennings.—Contributions to the Geological Study of County Waterford: the Lower Palæozoic Bedded Rocks of the Coast: F. R. Cowper Reed.

*THURSDAY*, MAY 11.

MATHEMATICAL SOCIETY, at 8.—The Zeroes of a Spherical Harmonic $P_n^m(\mu)$ considered as a Function of $n$: H. M. Macdonald.

*FRIDAY*, MAY 12.

ROYAL INSTITUTION, at 9.—Magnetic Perturbations of the Spectral Lines: Prof. Thomas Preston, F.R.S.

ROYAL ASTRONOMICAL SOCIETY, at 8.

MALACOLOGICAL SOCIETY, at 8.

## BOOKS, PAMPHLETS, and SERIALS RECEIVED.

BOOKS.—City and Guilds of London Institute, Report to the Governors, March 1899 (London).—Engine-Room Practice: J. G. Liversidge (Griffin).—Manual of Library Cataloguing: J. H. Quinn (Library Supply Company).—The Philosophy of Memory: Dr. A. T. Smith (Louisville, Morton).—The Flora of Cheshire. Lord de Tabley (Longmans).—Outlines of Zoology: Prof. J. A. Thomson, 3rd edition (Pentland).—The Phenomena of Nature: J. Walker, Part 2 (Sonnenschein).—Essai Critique sur l'Hypothèse des Atoms: Prof. A. Hannequin, deux édition (Paris, Alcan).—Graduated Test Papers in Elementary Mathematics: W. J. Wood (Macmillan).—Annual Report of the Smithsonian Institution, 1897 (Washington).—Milk: Dr. C. M. Aikman, 2nd edition (Black).

## *THE NATIONAL PHYSICAL LABORATORY.*

THE following Scheme for the government of the National Physical Laboratory has been drawn up by the Royal Society with the approval of Her Majesty's Treasury, and steps are being taken to give effect to the Scheme at as early a date as practicable. The Government has promised to ask Parliament for a grant of 12,000*l*. for buildings, and an annual grant of 4000*l*., and will also facilitate the erection of the buildings in the Deer Park at Kew. The resources of the Kew Committee of the Royal Society and the buildings used by them will also be handed over to the new Institution.

The grant will not be available until voted by Parliament, and the first grant will be 5000*l*. for buildings and 2000*l*. in respect of the first half-year. The Treasury have, however, approved of the immediate nomination of the new governing body, and have authorised any preparations for the work of the Laboratory, which can be undertaken without expenditure, previous to the sanctioning of the anticipated grants by Parliament.

The President and Council of the Royal Society have accordingly appointed the Executive Committee, in accordance with the provisions of the Scheme, with a view to preliminary arrangements being set on foot as soon as possible; and will shortly proceed to complete the constitution of the General Board. The representatives nominated by the technical Institutions named in the Scheme to serve on the General Board are as follows:—

| | |
|---|---|
| Mr. W. H. Preece, F.R.S. ... ...<br>Sir J. Wolfe-Barry, F.R.S. ... ... | Institution of Civil Engineers. |
| Sir Wm. White, F.R.S. ... ...<br>Sir Edw. Carbutt, Bart. ... ... | Institution of Mechanical Engineers. |
| Mr. Alex. Siemens ... ... ...<br>Prof. Ayrton, F.R.S. ... ... ... | Institution of Electrical Engineers. |
| Sir Wm. Roberts-Austen, F.R.S.<br>Sir Fredk. Abel, F.R.S. ... ... | Iron and Steel Institute. |
| Mr. Geo. Beilby ... ... ... ...<br>Mr. Walter F. Reid ... ... ... | Society of Chemical Industry. |
| Sir Nathaniel Barnaby ... ... ...<br>Mr. J. T. Milton ... ... ... ... | Institution of Naval Architects. |

The President and Council of the Royal Society have appointed as Vice-Chairman of the General Board and of the Executive Committee:

Lord Rayleigh, F.R.S.

The following are the other members of the Executive Committee:

| | |
|---|---|
| Lord Lister, President of the Royal Society.<br>Mr. A. B. Kempe, Treasurer of the Royal Society.<br>Prof. A. W. Rücker, as Secretary of the Royal Society.<br>Sir Courtenay Boyle, K.C.B., Permanent Secretary of the Board of Trade. | *ex officio.* |
| Capt. W. de W. Abney, F.R.S. ... ...<br>Capt. E. W. Creak, F.R.S. ... ...<br>Prof. G. Carey Foster, F.R.S. ... ...<br>Mr. F. Galton, F.R.S. ... ... ...<br>Prof. J. Perry, F.R.S. ... ... ...<br>Gen. Sir R. Strachey, F.R.S. ... ... | from among the Members of the Kew Observatory Committee. |
| Sir John Wolfe-Barry, F.R.S. ... ...<br>Sir Edward Carbutt, Bart. ... ...<br>Mr. Alex. Siemens ... ... ...<br>Sir William Roberts-Austen, F.R.S. ...<br>Mr. G. Beilby ... ... ... ...<br>Sir Nathaniel Barnaby ... ... ... | from among those Members of the General Board nominated by the technical Societies named in the Scheme; and |
| Prof. R. B. Clifton, F.R.S.<br>Prof. O. Lodge, F.R.S. ... ... ...<br>Sir Andrew Noble, F.R.S. ... ...<br>Prof. A. Schuster, F.R.S. ... ...<br>Prof. J. J. Thomson, F.R.S. ... ...<br>Dr. Thorpe, F.R.S. ... ... ... | Nominated by the President and Council of the Royal Society. |

The Scheme of Organisation of the Laboratory is as follows:—

1. The name of the Institution shall be the National Physical Laboratory. The Kew Observatory shall be incorporated therewith.

2. The ultimate control of the Institution shall be vested in the President and Council of the Royal Society, who, in the exercise thereof, may from time to time issue such directions as they may think fit to the General Board and Executive Committee hereinafter described. The President of the Royal Society shall be the Chairman of the Governing Body as hereinafter defined. The income and all other property of the Institution shall be vested in the Royal Society for the purposes of the Institution.

3. For the present, and until otherwise ordered by the President and Council of the Royal Society, with the approval of H.M. Treasury, there shall be a Governing Body for the Institution, consisting of a General Board and an Executive Committee, the constitution and duties of which shall be as hereinafter defined. Provided always that the Permanent Secretary of H.M. Board of Trade shall be *ex officio* a member of the Governing Body, and that the choice of members of the Governing Body, or of any Committee thereof, shall not be confined to Fellows of the Royal Society.

4. The General Board shall consist of the President, Treasurer, and Secretaries of the Royal Society, the Vice-Chairman of the Board (appointed as defined below by the President and Council of the Royal Society), the Permanent Secretary of the Board of Trade, and of thirty-six ordinary members.

Twenty-four of the ordinary members shall be appointed by the President and Council of the Royal Society; of the remaining twelve ordinary members, two shall be nominated for appointment by the Council of each of the following Institutions, as being fitted to represent commercial interests in connection with the Laboratory:—

The Institution of Civil Engineers.
The Institution of Mechanical Engineers.
The Institution of Electrical Engineers.
The Iron and Steel Institute.
The Institution of Naval Architects.
The Society of Chemical Industry.

In the selection of ordinary members of the General Board care shall be taken that Scotland and Ireland are represented.

Any person not being already a member of the General Board who shall become a member of the Executive Committee, shall be a member of that Board during his tenure of office on the Executive Committee, but shall be regarded as an additional, and not as an ordinary member of the Board.

5. The Executive Committee shall consist of the President, Treasurer, and one of the Secretaries of the Royal Society; the Vice-Chairman of the Executive Committee (appointed as defined below); the Permanent Secretary of the Board of Trade; six persons appointed by the President and Council of the Royal Society from among those who are members of the Kew Observatory Committee at the time when the Kew Observatory is incorporated in the National Physical Laboratory (two of these six persons shall retire at the end of every two years, and vacancies occurring amongst them by retirement or otherwise shall not be filled up); and of twelve ordinary members.

The ordinary members shall be nominated by the

President and Council of the Royal Society, but one-half shall be chosen from among those members of the General Board who have been nominated as fitted to represent commercial interests on that Board.

Those members of the Executive Committee who are Fellows of the Royal Society, shall be appointed by the President and Council to be the Gassiot Committee of the Royal Society.

6. The Vice-Chairman of the General Board shall be appointed by the President and Council of the Royal Society, and shall also be Vice-Chairman of the Executive Committee. He shall hold office for six years, and shall be eligible for reappointment, but shall not hold office for more than twelve years.

7. At least one-sixth of the ordinary members of the General Board and of the Executive Committee shall retire annually.

In the case of the General Board, the retiring ordinary members shall be those who have not attended a meeting of the Board for two years, together with so many other members of the Board, selected by seniority, as may be necessary to bring the number of retiring members up to one-sixth of the whole number of ordinary members of the Board.

In the case of the Executive Committee, the retiring ordinary members shall be those who have not attended one-half of the meetings of the Committee during the previous year, together with so many other members of the Board, selected by seniority, as may be necessary to bring the number of retiring members up to one-sixth of the whole number of ordinary members of the Board.

No retiring member of the General Board or of the Executive Committee shall be eligible for reappointment until at least one year has elapsed from the date of his retirement.

The President and Council shall have power to remove from the General Board and from the Executive Committee any member of either whom they may judge to be disqualified.

Vacancies on the General Board or on the Executive Committee due to death, resignation, or removal by the President and Council of the Royal Society, shall be filled by the President and Council of the Royal Society, provided always that—

(1) Any person so appointed shall, for the purposes of the regulations for retirement from the Board or Committee, be regarded at the time of his appointment as having served for the same period as the member to whose place he succeeds.

(2) If the vacancy on the General Board be caused by one of the persons nominated as fitted to represent commercial interests ceasing to be a member of the Board, the President and Council of the Royal Society shall choose his successor from among a list of names recommended by the Councils of the Institutions named in Section 4.

(3) If a vacancy on the Executive Committee be caused by one of the persons nominated as fitted to represent commercial interests ceasing to be a member of the Committee, his successor shall either be selected from among those members of the General Board who were nominated as fitted to represent commercial interests, or shall be nominated by the President and Council of the Royal Society after consultation with the Councils of the Institutions named in Section 4.

The President and Council of the Royal Society shall determine the order of the seniority of the members of the first General Board and of the first Executive Committee for the purposes of the regulations for retirement.

*The Executive Committee.*

8. The Executive Committee shall have the immediate management of the National Physical Laboratory; shall appoint and dismiss the officials, except the Director; and shall determine the nature of the work to be undertaken from time to time.

*The General Board.*

9. A meeting of the General Board shall be held in October, at which the Executive Committee shall present a report on the work and finances of the National Physical Laboratory during the year ending on the preceding September 30. Copies of this report shall be circulated among the Members of the General Board at least one week before the meeting, and after the meeting shall be forwarded to the President and Council of the Royal Society, together with any further report, resolutions, or recommendations which may be added by the General Board.

The Executive Committee shall also lay before the General Board at its meeting in October a statement as to the work which it is proposed to undertake in the Laboratory during the ensuing year. This statement shall be circulated among members of the Board at least a week before the meeting; and the General Board may make such recommendations relative to the statement, or to the future work of the National Physical Laboratory, as they may think fit.

These recommendations shall be laid before the Executive Committee for their consideration.

*Sub-Committees.*

10. The Executive Committee may from time to time appoint Sub-Committees, of which the members shall not necessarily be members of the Executive Committee or of the General Board, either to superintend or to assist in certain specified investigations, or to superintend some department of the National Physical Laboratory.

*The Director.*

11. The Director of the National Physical Laboratory shall be appointed by the President and Council of the Royal Society after consultation with the Executive Committee, on such terms as the President and Council may determine, and shall be removable by the President and Council. He shall be responsible to, and shall take instructions from, the Executive Committee, but, subject to such instructions, he shall have the sole direction and control of the officials of the National Physical Laboratory and of the work done within it.

The Executive Committee may delegate its power of appointing and dismissing the officials of the Institution to the Director in such cases as it may think fit.

The Director shall neither be allowed nor be called upon to undertake work not connected with the National Physical Laboratory, except with the consent of the Executive Committee.

*Finance.*

The Royal Society shall open a banking account, to be called "The National Physical Laboratory Account of the Royal Society," into which all sums received by the Executive Committee for the purposes of the Institution shall be paid. The Treasurer of the Royal Society shall also pay into this account all sums received by him for the said purposes, after deducting therefrom such amounts as he shall be directed by the President and Council, with the approval of the Treasury, to retain for the purpose of defraying any expenses which the Royal Society may incur in the exercise of its control of the Institution.

The Executive Committee shall be empowered to draw on this account for the purposes of the Institution by

cheques signed by such members of the Executive Committee as may be authorised by the Committee to do so.

*Legal Proceedings.*

Any legal proceedings with regard to the affairs of the Institution, which it may become necessary to institute or defend, shall be instituted or defended by the Solicitors of the Royal Society, in the name and on behalf of the Royal Society upon the instructions of the Executive Committee, but no such proceedings shall be instituted or defended without the order of the President and Council of the Royal Society.

*The Kew Observatory Committee of the Royal Society.*

"The Kew Observatory Committee of the Royal Society," incorporated under the Companies Act, 1867, shall be wound up; and the property thereof shall be held by the Royal Society for the purposes of the Institution.

## CHEMICAL TECHNOLOGY.

*Outlines of Industrial Chemistry.* A Text-book for Students. By Frank Hall Thorp, Ph.D., Instructor in Industrial Chemistry in the Massachusetts Institute of Technology. Pp. xx + 541. (New York: The Macmillan Co. London: Macmillan and Co., Ltd., 1898.)

IN writing a book such as the present, the author's main difficulty must be in deciding what to omit. The number of industries in which chemistry plays a more or less important part is so large, and their nature so varied, that it would appear to be almost impossible to give even a moderately satisfactory account of them within the limits of one volume. By omitting metallurgy altogether, and condensing the preparation of the artificial organic dye-stuffs into a little over eight pages, the author succeeds in finding space for the essentials of the majority of the remaining chemical industries. The omission of metallurgy is justified by the facts that this subject is usually taught independently, and that several good short text-books dealing with it already exist. The hemistry of the artificial organic colouring matters is generally included in courses of lectures on organic chemistry, and, presumably for similar reasons, no mention is made of the majority of the pharmaceutical and photographic chemicals.

An introductory section contains a general account of the apparatus employed in performing such common operations as evaporation, filtration, distillation, calcining, and so on, on the large scale. The diagrammatic sketches employed in this section, and throughout the book, are very clear and are calculated to be of much more service to a student than elaborate illustrations of the outside of the apparatus or even complicated working drawings would be. The two cuts on pp. 12 and 13, representing filter-presses, might with advantage have been replaced by diagrams.

After a brief account of the main facts about fuels and water, the different chemical industries are considered, about equal space being devoted to those dealing with norganic and those dealing with organic substances. The accounts of the origin and properties of the raw materials, and of the different operations and transformations through which they pass on their way to the finished products, are clear and concise; in most cases the author has succeeded admirably in subordinating mere detail whilst bringing out clearly the essential factors on which the success of the process depends.

The treatment of some of the more recent developments of technical chemistry is not quite so satisfactory as that accorded to the older industries; the account of the electrolytic processes for the preparation of alkalis and chlorine being perhaps the least satisfactory chapter in the book. The author of a work on industrial chemistry is, of course, hampered to some extent by the natural and inevitable reticence of the inventors of new processes; but, even allowing for this, the chapter might have been improved by a wider acquaintance with the recent literature of the subject. This, in passing, is true, though to a less extent, of the chapter dealing with the cyanide industry in which so much progress has been made of late years.

In speaking of the Deacon chlorine process, on p. 99, the author remarks that since the reaction between hydrochloric acid and oxygen evolves heat, the temperature of the tower in which the reaction occurs should "theoretically" be maintained without further heating, but that this is not the case. In reality, of course, the whole thing depends on the relation between the amount of heat evolved by the chemical change and that lost by radiation, convection, and conduction. He goes on to say:—

"Theoretically, too, all the chlorine of the hydrochloric acid should be recovered, but practically the reaction is far from complete."

Since it is well known that the reaction

$$2HCl + O = H_2O + 2Cl$$

is reversible, an equilibrium must tend to be established; this equilibrium will not be displaced by the presence of a catalytic agent (which merely accelerates the velocity with which the equilibrium is approached), so that the practical result is only in disaccord with the incorrect theory.

These are, however, but minor blemishes in a book which attains a very high average of excellence. We are not acquainted with any other book in English which covers the same ground, and there is no doubt that it will prove to be of great service to all persons interested in technical chemistry, and more especially to the students and teachers to whom it most directly appeals. T. E.

## VOLCANOES.

*Volcanoes: their Structure and Significance.* By T. G. Bonney, D.Sc., LL.D., F.R.S., Professor of Geology at University College, London. Pp. 337. With 12 Plates, a Map, and 21 Illustrations in the Text. "The Progressive Science Series." (London: John Murray. New York: G. P. Putnam's Sons, 1899.)

IN this work the author has succeeded in giving, within convenient limits, a clear and very readable account of the present state of vulcanological science. The work is not burdened with scientific details nor made unattractive by a too technical terminology; but it nevertheless contains a trustworthy discussion of the most recent researches of geologists, and their latest views upon questions connected with these very interesting natural phenomena.

The first chapter, entitled "The life-history of vol-

canoes," contains succinct descriptions of a number of celebrated volcanic outbursts, including that of Vesuvius in A.D. 79, and later eruptions, of Monte Nuovo in 1538, of Stromboli, Bandai-san in Japan, Galoongoon in Java, Krakatoa, Kilauea in the Sandwich Islands, Skaptar Jökull in Iceland, Cotopaxi, Graham Island, and Bogosloff in Behring's Sea; lastly, of the mud volcanoes of Baku, and of Krabla in Iceland, and the geysers of the Yellowstone Park. These examples are admirably chosen to illustrate the varied manifestations, and successive phases of volcanic activity, and serve at the outset to give the student a clear idea of the nature and sequence of the phenomena, which it is the object of the work to explain.

The second chapter deals with "The products of volcanoes," and in it the author has evidently experienced some difficulty in maintaining the popular character of the work, while at the same time supplying accurate petrographical information. The explanation of mineral and rock names being relegated to a glossary, a fairly complete sketch is given of the classification and nomenclature of the igneous rocks. The admirable photographs of rock-sections in this part of the work serve to make the descriptions more intelligible.

In the third chapter, on "The dissection of volcanoes," an account is given of the results obtained from the study of volcanic piles in various stages of degradation under the agencies of denudation. Commencing with the "puys" of Auvergne, which Prof. Bonney describes from personal observation, and going on to the Eifel with its crater lakes, the great lakes of Central Italy and Oregon are alluded to, and then the more or less ruined volcanic cones, and crater rings of Santorin, Etna, and other districts are referred to, to illustrate the salient features of volcanic structures; and in the end illustrations are taken from the still more ruined volcanoes of central Scotland and Hungary, and from the structures which have received the name of laccolites in the western territories of the United States, and the midland district of England.

The next chapter is on "The geological history of British volcanoes," and attempts a chronological sketch of volcanic activity in the British Islands. Prof. Bonney in the main adopts the results arrived at on this subject by the officers of the Geological Survey, though he points out that many of their conclusions are not free from doubt. The sixth chapter, which gives a sketch of "The distribution of volcanoes," brings the descriptive portion of the book to a close. In this part of the work, much information has been incorporated which has been obtained by travellers and others during the last twenty years, and since the time at which most of the earlier English treatises on vulcanology have appeared. The general account of volcanoes all over the globe, with the discussion of the main features of their geographical distribution, is as complete and full as could be expected in some eighty pages, and enables the author to marshal a number of facts which are of the greatest service in leading up to the theoretical speculations to which the seventh and last chapter are devoted.

In referring to Prof. Bonney's remarks upon volcanic theories, it is only fair to point out that he himself admits that he is unable to supply "any complete theory of vulcanicity," and that he thinks we must wait for some time before any such theory, which will satisfy all the conditions of the problem, will be found. To use his own words:—

"We are, I think, in this position: We have ascertained a number of important facts; many of these suggest conclusions, but some of the latter seem at present difficult to reconcile and harmonise. Indeed it is my opinion that either some link in the chain of evidence still remains to be discovered, or the relation of those which we know is not yet fully understood. In other words, we do not seem to be in a position to put forward a complete explanation of vulcanicity. Nevertheless, I am sanguine that, to borrow an appropriate phrase from a child's game, 'we are getting warm,' and that our successors, by the end of the first quarter of the coming century, will have got much nearer to the solution of the problem."

In spite of this disclaimer on the author's part of any ability to propound a complete theory of vulcanicity, the concluding chapter of the work may be scanned alike by the general reader and the student of science with much profit. An account is given of numerous speculations upon the various portions of the question of vulcanicity, which have of late years attracted considerable attention, and the author's criticisms and suggestions are well worthy of perusal and consideration.

The volume, which is one of the handsome "Progressive Science Series," is admirably printed and fully illustrated; it constitutes a valuable addition to the popular books of science of the day. J. W. J.

## OUR BOOK SHELF.

*Recueil de données numeriques publié par la Société française de Physique, Optique.* Par H. Dufét. Deuxième Fascicule. Propriétés optiques des Solides. Pp. vi + 367. (Paris: Gauthier-Villars, 1899.)

THE data collected in this volume should prove of value in physical and chemical laboratories. The first section contains the indices of refraction, and their variation with temperature, of calcite, quartz, fluorine, rock-salt, sylvine (potassium chloride), and common alum. The second collection of tables comprises determinations of the refractive indices, at ordinary temperatures and for various wave-lengths, of glasses of known chemical composition. The optical properties of solid inorganic substances are tabulated in the third section, and of organic bodies in the fourth. These two sections occupy the greater part of the volume, and they should be of particular service to mineralogists and chemical crystallographers. Tables on the influence of temperature on the optical properties of solids, and on the indices of some metals and metallic compounds conclude the work.

*The Natural Mineral Waters of Harrogate.* By F. W. Smith, M.D. Pp. 101. (London: Dawbarn and Ward, 1899.)

DR. SMITH considers the natural waters of Harrogate chemically, therapeutically, and clinically, with reference to their suitability for drinking and bathing purposes. He maintains that the springs of Harrogate compare very favourably with those of Baden-Baden, Homburg and Kissingen, and that there is no need for invalids to run the risk of a journey to the Continent. Full analyses, by trustworthy chemists, are given of all the varieties of mineral waters with which this Yorkshire spa is endowed, and much valuable information concerning the local rainfall, temperature and mortality should cause this well-illustrated volume to take its place as a handy guide for "the doctors of this country," to whom Dr. Smith dedicates his work.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### A Measure of the Intensity of Hereditary Transmission.

THE possessors of certain hereditary characters are unquestionably *sub-prolific;* that is, they eventually contribute less than their average share to the stock of the future population. It may be that they die before the age of marriage, or that they are sexually unattractive or unattracted, or that if married they are comparatively infertile, or that if married and fertile the children are too weakly to live and become parents. It is very probable, though I have no trustworthy facts to confirm the belief, that persons affected with hereditary insanity are sub-prolific because their families, if they have any, are apt to contain members who are afflicted in various ways that render them less likely than others to live and to marry. But I do not propose to go into the details of this or of any other malady, but merely mention it as an illustration of what is meant, when I assume that the possessors of some particular characteristic, not necessarily a morbid one, and which may be called A, are sub-prolific on the average.

It is a familiar statistical fact that the characteristics of a population, taken as a whole, who live under uniform conditions, change very little during many successive generations. So many per million of them are always found to be affected in this way, so many per million in that. The birth-rate continues the same, so does the death-rate; similarly as regards the various kinds of accident, and also, it may be inferred, as regards each form of disease, though it would be difficult to prove this in all cases, owing to improvements in diagnosis and nomenclature which make the statistics of disease for one period not comparable on strictly equal terms with those of another. It is therefore reasonable to discuss what might occur in an ideal population, which we will call P, whose characteristics are absolutely unchanged during successive generations, and to make such small corrections in the results as the conditions may require when dealing with real populations.

P and A being thus defined, it is obvious that the characteristic A must be transmitted with exceptional intensity in P. The possessors of A leave comparatively few descendants, consequently those few must be over-richly endowed with A; otherwise the number of the possessors of A would steadily diminish, and a P population would be impossible. Wherever a P population occurs, there must exist an inverse relation between the intensity with which A is hereditarily transmitted, and the prolific faculty of those who possess it.

This consideration may be of practical importance to actuaries in enabling them to estimate more justly than at present, the weights to be assigned to different hereditary diseases. It is a most difficult and delicate matter to attack this question directly, namely by making exhaustive inquiries into the life-history of all the near relatives of those who suffer from any serious hereditary malady. The difference in the results arrived at by different inquirers proves this, and shows the need of some second and independent method of investigation. The above considerations supply such a method in all cases where the frequency of the disease is found to have been approximately constant during successive generations of the population taken as a whole.

All that will then be needed, is to find how far those affected by the disease in question have been prolific, testing their capacity in that way by the number of their adult descendants in (say) the *second* generation, those in the first generation indicating little more than their fertility, which, as the children may be weakly, is not the same thing as the capacity of the parents for contributing to the future population. When the descendants in the second generation are neither more nor less numerous than the generality, the intensity of the transmission of the disease would be the same as that of any neutral quality, such as a moderate difference of stature. But if those descendants were more numerous than the generality, the intensity of transmission must be less than the average, while if the descendants were less numerous, the intensity would be greater.

It must be clearly understood that this method is of general application, and is not intended to be confined to morbid characters only. FRANCIS GALTON.

### Triboluminescence

THE interesting list of substances mentioned in to-day's review in NATURE of a paper on the subject of the above phenomenon, mentioning as substances in which it is conspicuous, cane-sugar, saccharin, hippuric acid, and some still more complex organic bodies, might lead one to suppose that only substances of an organic nature, in a crystalline state exhibit the kind of triboluminescence seen as a flash of light when a crystal of such substances is crushed between two glasses. But this is not quite exclusively the case, because crystals of uranium-nitrate, and perhaps other crystallised salts of uranium, emit a very bright greenish-yellow flash when pressed to pieces between glass plates. The property seems permanent in these crystals, and it is also apparently independent in them of chemical impurities, since any crystallised sample of the nitrate, as far as I have tried, shows the light flash very strongly, without any apparent loss of brightness by long keeping.

The ruddy light which gleams from under glass or from a flint pebble when ground with strong pressure on a grindstone, must apparently be a true example of luminescence produced by friction, since it is equally visible under water on a thoroughly wet, as on a dry, grindstone, where it can hardly be supposed to result from high temperature producing actual incandescence. But examples of crystals which emit light by fracture do not, it appears, present themselves in nearly such abundance among mineral substances, as they have now been shown in the above-mentioned paper to do in so many cases among organic bodies.

A rather interesting observation of thermoluminescence once befel me while making trials of that property in minerals; and as it may afford, perhaps, a ready means of tracing lime or calcareous ingredients in certain minerals, it may be useful to mention it here, although the mode of excitation used in that instance was not by crushing or rubbing, but by heating the material. Some fine dust and grains obtained from the interior portion of the mass of the Middlesborough aërolite, when the meteorite was first being chemically and microscopically examined, were found, to my considerable surprise, to glow quite distinctly, though not very brightly, with yellowish-white light, when sprinkled in the usual way for these experiments on a piece of nearly red-heated iron in the dark. No such luminescence would, I believe, be evolved by that means from pure terrestrial specimens of the pair of double silicates of magnesia and iron (olivine and bronzite, much less from the moderate sprinkling of nickel iron, and perhaps of iron-sulphide found with them), of which the stony matter of the meteorite in the main consists. But as its stony mass was considered, in the exact chemical analysis of the meteorite made by Dr. Flight,[1] to contain probably, besides, an appreciable amount of labradorite or lime-felspar, the source of the light may have been this calcareous ingredient of the stone, as calciferous rocks and minerals, for the most part, shine brightly with various shades from light- to reddish-yellow, in the dark, when strongly heated. To whatever chemical materials in the stone, however, the light was really due, it afforded, at all events, clear proof that no heat of exceedingly high temperature can ever have penetrated to the interior of the meteorite, even when it was passing at its fall, in a fireball through the atmosphere, since the time when it was broken off from some parent rock and projected on a celestial course about the sun; for a very moderate degree of heat suffices to expel completely from minerals of these luminescent natures all the store of thermoluminescent energy which, either originally communicated to them from without by radiation near some exposed or denudated surface, or else contracted by them in some more mysterious way at great subterranean depths, they more or less abundantly possess. A. S. HERSCHEL.

Observatory House, Slough, April 27.

### The New Zealand Godwit (*Limosa novæ-zelandiæ*).

THE Maori of New Zealand have an ancient saying or proverb, "Who can tell where the kuaka (the godwit) has its nest?" No doubt the Maori were well acquainted with the singular habit of these birds, in that they leave the shores of New Zealand, for a distant land across the seas, about the same time that other migratory birds, which have wintered on the Pacific Islands located nearer the tropics, are nesting and

[1] *Proceedings* of the Royal Society, vol. xxxiii., p. 347, February 1882.

rearing their young in the New Zealand forests, to which country they periodically return for the summer season. Such, for example, are the long-tailed cuckoo and the small bronze-cuckoo, known to the Maori as "the bird of Hawaiki"—that is, the bird who returns to the land from whence the Maori ancestors originally came.

Our kingfisher also moves northward in the autumn, and may likewise leave for a warmer country. These latter birds conduct their migrations as we should expect—that is, they reverse the conduct of their flight to those birds which live in northern latitudes, and we feel that their natural instincts are working according to rule. But the kuaka, not satisfied to pass the winter in a warmer country, must actually have two summers—one in New Zealand and a second in Northern Siberia, where it is said to have its breeding-place. Any way, it leaves in countless numbers from the north-east point of New Zealand, from almost the very place where the spirits of the dead Maori are supposed to take their departure to the other world (Reinga). For which reason the bay on the shore of which the birds assemble before flight is named by Europeans "Spirits' Bay."

The Polynesian mariner may in former times have guided his migrations by observation of the place of departure and arrival of birds of passage, also from the particular dates of such occurrence, and from the circumstance that the winds at that time were most favourable for travel in such particular directions. The spirits of their dead may have been supposed to return to the original birthplace of the race; and the nearest point of departure would be that from which the birds also departed.

But do any migratory birds other than the kuaka go further north than Tahiti, Rarotonga, Samoa, and the Fijis?

I always understood that no bird from either the north or the south temperate zones ever voluntarily crossed the tropics, and to me it seems a fable that even the kuaka should do so.

Whence comes the hereditary knowledge that should lead the kuaka half over the world to find a suitable breeding-place? Why does it not go in search of an Antarctic continent, as should be the natural sequence of events? Are not the high lands and alpine valleys of New Zealand where the dotterel, the red-breasted plover, the stilt-plover, oyster-catcher, &c., make their nests, equally suitable for the godwit?

Where does the European godwit (*Limosa lapponica*) breed? and is it not said that the nesting-place of the European knot (*Tringa canutus*) has never been discovered?

That the New Zealand godwit starts in a northerly direction in its migration is assured; but who has traced its course onward, as following the shores of China, it is making its way to lonely steppes in Siberia?

That these birds should winter during a New Zealand summer, and then leaving should pass through both temperate and torrid zones, and still onward to the confines of the north frigid zone to nest and summer, is truly marvellous. Will any reader of NATURE kindly contribute to our knowledge of the nesting-place of the godwit or the knot, or remark on other points at issue?

TAYLOR WHITE.

Wimbledon, Hawkes Bay, N.Z., February 9.

[In reference to the above, the British Museum possesses a single egg of the knot, said to be one out of a clutch of four obtained at Disco Island, Greenland. Colonel Feilden has good grounds for believing that this bird nests in the New Siberian Islands.—ED.]

## The Indian Musk-Shrew.

THE old yarn about the tainting of wine in bottle by the common Indian shrew (*Crocidura coerulea*)) seems to die hard, since "W. T. B." has had to correct it again in your issue of this week. The account of a crucial and deliberate experiment may be another nail in its coffin.

I kept wine in small chambers off my office, in a locked basket, ventilated at the ends, for use at luncheon. One day I opened it, and found a musk-shrew coiled up on a napkin, and did not disturb him, nor he himself. Next day I impanelled an unconscious jury; and we found the wine perfectly good. The musk-rat had been there in the morning, but had received a quiet hint to go. When my guests were gone, I wiped a glass with his napkin, filled it with wine from the same bottle, and found this too musky to swallow.

The wine was a sound Pommard from Treacher and Co., Bombay, with capsuled corks bearing their stamp.

I do not know whether it was bottled in Europe or in India.

I believe that the commonest cause of the musk-taint in wine is the wiping of the glass with a clout that has been picked up out of a corner, where the musk-shrew has laid on it.

Even in the best houses in India native servants will often use very little care about the cleanliness of "glass-cloths"; and when one that has served to clean a lamp or shelter a shrew is next used upon a wineglass, you have *vera et sufficiens causa* for spoilt wine—and temper.

I have a note on this somewhere in the *Journal* of the Bombay Natural History Society; but it is buried out of sight in some back volume, as my experiment took place about twenty years ago. I may add that the place of it was Ahmadabad, in Gujarat.

W. F. SINCLAIR.

102 Cheyne Walk, Chelsea, London, S.W., May 5.

## Mammalian Longevity.

SINCE my letter on this subject in NATURE of March 23, I have noticed that a slight change in the formula—the reduction of the constant from 10·5 to 10·1—gives much better results. The agreement is now very close indeed. The amended statement now runs as follows:—

The full term of life in any mammalian species is equal to 10·1 times its period of maturity divided by the cube root of the period, or 10·1 times the cube root of the square of the period.

We get the following results from its application:—

| Animal. | Observations. | | | f. t. l. by formula. | Other observations. |
|---|---|---|---|---|---|
| | Authority. | p. m. | f. t. l. | | f. t. l. |
| Dom. Mouse .. | Dr. Ainslie Hollis. | ·25 yr | 4 yr. | 4 (4·01) | |
| Guinea-pig ... | Flourens. | ·583 | 6–7 | 7 (7·05) | |
| Lop-Rabbit— | | | | | |
| Buck... ... | R. E. Edwards. | ·75 | 8 | 8 (8·3) | |
| Doe ... ... | R. E. Edwards. | ·67 | 8 | 8 (7·7) | |
| Goat ... ... | Pegler. | 1·25 | 12 | 12 | |
| Fox ... ... | St. G. Mivart. | 1·50 | 13–14 | 13·25 | |
| Cat ... ... | Jennings. | 2 | 15 | 16 | |
| Cattle ... ... | Dr. Ainslie Hollis. | 2 | 18 | 16 | 14, Gresswell. 15-20, Flourens. |
| Large Dogs ... | Dalziel. | 2 | 15 | 16 | 15-20, Flourens and others. |
| Thor. Horse ... | Dr. Ainslie Hollis. | 4·5 | 30 | 28 | |
| Pigs ... ... | James Long. | 5 | 30 | 30 | |
| Hippopotamus | Chamb. Encyc. | 5 | 30 | 30 | |
| Lion ... ... | St. G. Mivart. | 6 | 30–40 | 33 | |
| Hunter... ... | Blaine. | 6·25 | 33 | 34 | |
| Arab Horse ... | Dr. Ainslie Hollis. | 8 | 40 | 40 | |
| Camel ... ... | Flourens. | 8 | 40 | 40 | |
| Man ... ... | Buffon. | 25 | 90–100 | 86 | 100, Flourens. 75, Farr. |
| Elephant ... | Darwin. | 30 | 100 | 98 | |
| Elephant ... | C. F. Corder and Indian hunters. | 35 | 120 | 108 | 100, Darwin. |

In this table, p. m. stands, as before, for period of maturity, and f. t. l. for full term of life.

In the first table another statement dealing with the cat was also given, on the authority of Dr. Mivart, which is excluded from this, since the period mentioned—one year—obviously refers to the animal's period of puberty, not its period of maturity, as is indicated by Dr. Mivart's expression: "The domestic cat begins to be ready to reproduce by the end of the first year of her life. . . ."

The age of the hunter, calculated from Blaine, was given in the previous table at thirty-five, and in this it is given at thirty-three. Blaine states that a horse of thirty years is relatively as old as a man of eighty, and a horse of thirty-five as a man of ninety. The first formula gave about ninety for man, and the corresponding age for the horse was therefore thirty-five; but the corrected formula gives eighty-six for man, which corresponds to thirty-three in the horse.

I agree with Dr. Ainslie Hollis that Buffon's 90–100 years for man is too long; but, on the other hand, seventy-five—the period given by Dr. Hollis from Dr. Farr's calculations—seems much too short. The great majority of persons have their lives cut short by disease, the nervous strain of life, &c., and do not live to anything like the full term of life. Were it not for such influences as these, most persons at seventy-five would probably still possess a considerable degree of vitality, and should be able to look forward to many years of life. Furthermore, Farr's cal-

culation is based on what seems a faulty method. The average of life, about fifty years, is taken, and the expectation of life (in reality a somewhat larger figure), twenty-five years, is added, making up seventy-five, the manifest assumption being that the full term of life of a species is equal to its *average* life plus the *expectation of life* at that age, a conception for which I know of no physiological justification. Eighty-six to eighty-seven years, the period given by the formula, probably represents with fair accuracy the average age at which people would pass from life by senile decay if their lives were not shortened by deleterious influences and conditions. ERNEST D. BELL.

### "Primitive Constellations."

REFERRING to your reviewer's hostile notice of my work, "Primitive Constellations," I have seldom realised the strength of my general position until I have seen some attack on it. Against my main contention, *i.e.* the identity of various Greek and Babylonian constellations, he has nothing to say, except that I start with my "theory ready made." Really, he does me much honour. Am I the inventor of the "theory" that, *e.g.*, the signs of the Zodiac were derived from Babylonia? But, leaving nine-tenths of the book with merely a little abuse, he has much to say on the transliteration of Babylonian words, and expresses great scorn because, following Prof. Sayce, I deliberately write *sa*, and not *sha*, and so on. He says I "really ought to know there is no *h* in Assyrian." Indeed. I am at present away from books, but happen to have Sayce's "Assyrian Grammar" at hand. At p. 46 I read, "*a, ha* . . . *h.* , *ah, hi, h.*" Again, I am perfectly aware of the force of "the determinative particle *ki*," and, in a book for general readers, have naturally chosen to write "Barsipki," not "Barsip$^{ki}$," "Suanaki," "Tintirki," &c. If the critic had endeavoured to refute my general proposition, or had carefully examined my treatment of any particular constellation figure, *e.g.* the *Arrow*, how much more useful it would have been. But a policy of pin-pricks does not venture on this.

Berry Pomeroy, Boscombe, April 18. R. BROWN, JUN.

THE writer of the review did not suggest that Mr. Brown had discovered the Babylonian origin of the signs of the Zodiac. The theory which the reviewer laid to his charge was to the effect that the Greeks of the pre-Homeric and Homeric ages had a full knowledge of the constellations known to their descendants in Ptolemaic times; and, further, that they obtained such knowledge at this early period from the Babylonians through intercourse with the Phœnicians and the "Hittites." It is from this theory that the reviewer entirely dissents. Mr. Brown's wholesale assertions that representations of animals in early Greek art are astronomical symbols it was thought might be charitably explained by supposing that he began his studies with this part of his theory "ready made." Of the two cuneiform signs which Mr. Brown cites as proving the existence of the *h* in Assyrian, the first only represents the vowel *a*, the second is only used to indicate the smooth breathing; that he should rely on a grammar published more than twenty years ago shows that he has not made himself acquainted with the recent literature on this subject. It is satisfactory to learn that Mr. Brown is aware of the force of the determinative particle *ki*; but to transliterate such a determinative (which was not pronounced) as though it formed a syllable of the word to which it is attached is, to say the least, misleading—particularly so in a book for general readers. Mr. Brown's numerous blunders in citing Hebrew, Phœnician, and Assyrian words, show that he is not acquainted with these languages at first hand; and it was stated that such a knowledge is essential to a writer who treats the subject of Babylonian astronomy from the linguistic side.

## *THE ROYAL SOCIETY SELECTED CANDIDATES.*

THE following are the names and qualifications of the fifteen candidates selected by the Council of the Royal Society, to be recommended for election into the Society this year:—

W. F. BARRETT,

F.R.S.E., M.R.I.A., Professor of Experimental Physics in the Royal College of Science for Ireland, Memb. Physical Society, Royal Dublin Society, and of General Committee of the British Association. Author of numerous original investigations and papers; amongst them are:—"The discovery of certain physical phenomena produced by the contact of a hydrogen flame with various bodies, and its application as a delicate chemical re-agent" (*Phil. Mag.*, November, 1865); "The discovery and investigation of a serious source of error in the determination of the absorption of heat by liquids" (*ibid.*, September, 1868); "The discovery and investigation of sensitive flames" (*ibid.*, March and April, 1867); "The application of sensitive flames as a delicate acoustic re-agent in illustrating the laws of the reflection, refraction, and interference of sound-bearing waves and the detection of inaudible vibrations" (*Proc. Roy. Dubl. Soc.*, January, 1868; *Science Review*, April, 1867; NATURE, May, 1877); "The discovery of recalescence and other molecular changes in iron and steel when raised to a bright heat" (*Phil. Mag.*, December, 1873; Brit. Assoc., 1890); "The investigation of the molecular changes accompanying the magnetisation of iron, nickel, and cobalt, and the discovery of the retraction of nickel, and the elongation of cobalt by magnetisation, with the determination of its amount" (*Phil. Mag.*, December, 1873, and January, 1874; Brit. Assoc., 1873, 1874, and 1882; *The Electrician*, October, 1882; NATURE, October, 1882); "The investigation of the magnetic properties and the determination of the physical constants of various alloys of manganese steel" (Brit. Assoc., 1887 and 1889; *Proc. Roy. Dubl. Soc.*, November and December, 1889, March, 1886, and in *The Electrician*). Also brief papers on the spheroidal state (*Proc. Roy. Dubl. Soc.*, December, 1877); on the magnetic properties of columnar basalt (*ibid.*, December, 1889), and on the magnetic moment of ingots of manganese steel (*ibid.*, December), &c.

CHARLES BOOTH,

Hon. Sc.D. (Camb.), Merchant and Shipowner. As having applied Scientific Methods to Social Investigation, exemplified by:—(1) A Study of Changes in the Occupations of the People in England, Scotland, and Ireland, from 1841 to 1881 (*Journ. of Statistical Soc.*, 1886); (2) A Study of the Condition of the Aged Poor in England and Wales from Official Statistics and Extended Private Enquiry ("The Aged Poor," Macmillan, 1894); (3) A Study of the Condition of the People of London, 1889 to 1899, in twelve volumes, of which nine are already published ("Life and Labour of the People in London," Macmillan).

DAVID BRUCE,

M.B., Surgeon-Major, Army Medical Staff. Has made important investigations relating to the nature and causes of Malta Fever, and discovered the micro-organism which is the cause of that disease, and proved its nature by experiment. Has successfully investigated the endemic disease of horses in Zululand, and proved the agency of the Tsetse Fly in producing it. Author of the following papers: "Discovery of a Micro-organism in Malta Fever" (*Practitioner*); "Sur une Nouvelle Forme de Fièvre rencontrée sur les Bords de la Mediterranée" (*Annales de l'Inst. Pasteur*); "On the Epidemic of Cholera in Malta during 1887" (*Trans. Epidem. Soc.*); "Report (to the Governor of Natal) on the Tsetse Fly Disease or Nagana" (1897); and a previous Report on the same subject; "Ueber die Virulenzsteigerung des Cholera Vibrio" (*Centralblatt f. Bacteriologie, &c.*). Eminent in Pathology and Bacteriology.

HENRY JOHN HORSTMAN FENTON,

M.A. (Camb.). Author of several papers on the action of hypochlorites and hypobromites on urea and other nitrogen compounds. Has made the remarkable discovery that hydrogen peroxide, although inactive alone, in presence of an iron salt, at once oxidises tartaric and other similar acids, carbohydrates, &c., giving rise to very characteristic products—a discovery of special importance in connection with plant metabolism, which he has elaborated with particular skill and thoroughness. His results are described in the following papers:—"Oxidation of Tartaric Acid in Presence of Iron" (*Trans. Chem. Soc.*, 1894); "A New Method of obtaining Dihydroxytartaric Acid, and the use of this Acid as a Re-agent for Sodium" (*ibid.*, 1895); "New Formation of Glycollic Aldehyde" (*ibid.*); "The Constitution of a New Dibasic Acid resulting from the Oxidation of Tartaric Acid" (*ibid.*, 1896); "A New Synthesis in the Sugar Group" (*ibid.*, 1897); "Properties and Relationships of Dihydroxytartaric Acid," I. and II. (*ibid.*, 1898); "The Oxidation of Polyhydric Alcohols in presence of Iron" (*ibid.*, 1899).

JAMES SYKES GAMBLE,

M.A. (Oxon.), F.L.S. Conservator of Forests, School Circle, N.W. Provinces, India, and Director of the Imperial Forest School, Dehra Dun. Fellow of the University of Madras, and *ex-officio* Fellow of the University of Allahabad. Author of a List of Trees, Shrubs, &c., of the Darjeeling District, Bengal (1st edit., 1877; 2nd edit., 1896); a Manual of Indian Timbers, published in 1881; a Monograph of the Bambuseae of British India, 1896. Also many papers on Forestry and on Botanical subjects in the "Indian Forester," which he has long edited.

ALFRED CORT HADDON,

M.A., M.R.I.A., F.Z.S. Professor of Zoology, Royal College of Science, Dublin. Vice-President of the Royal Zoological Society of Ireland. Member of Council of the Royal Dublin Society, Anthropological Institute and Folk-lore Society. Has considerably extended our knowledge of the Marine Fauna of Ireland (*Proc. Roy. Irish Acad.*, 1886–87). Received a grant from the Royal Society and spent eight months (1888–89) in studying the Marine Zoology, Geology and Ethnography of Torres Straits. Has made investigations upon British and Tropical Actiniaria (*Journ. Linn. Soc.*, xxi.; *Proc. Roy. Dubl. Soc.*, 1885–92, *Trans.*, 1889–92). Is the author of a memoir on "The Air-bladder and Weberian Ossicles in Siluroid Fishes" (with Prof. Bridge) (*Phil. Trans.*, 1893); "Report on the Polyplacophora collected by H.M.S. *Challenger* (Part XLIII., 1886); "Notes on the Development of Mollusca" (*Quart. Journ. Micros. Sci.*, 1882); and other papers on Marine Zoology. Has made a map and a geological survey of the Murray Islands, Torres Straits, which, with other geological observations, are published in the *Trans. Roy. Irish Acad.* in a joint memoir with Prof. Sollas and Prof. Cole. Has carried out extensive and detailed anthropological investigations on the mode of life, handicrafts, religion, and languages of the natives of Torres Straits (*Journ. Anthrop. Inst.*, 1891; *Proc. Roy. Irish Acad.*, 1893; *Folk-lore*, 1890; *Internat. Arch. f. Ethnogr.*, 1892–93). Has organized a scheme for the systematic study of Irish Ethnography (the Ethnography of the Aran Islands; Studies in Irish Craniology—Part I. Aran, II. Inishbofin. *Proc. Roy. Irish Acad.*, 1893–94). Has made an elaborate study of the evolution and degeneration and geographical distribution of the Decorative Art of British New Guinea (Cunningham Memoir Roy. Irish Acad.).

HENRY HEAD,

M.D. (Cantab.), M.A., M.R.C.P., M.R.C.S. Author of the following papers:—"Ueber positive und negative Schwankungen des Nerven Stromes" (*Pflüger's Archiv*, 1887); "Regulation of Respiration," Parts I.–II. (*Journ. Physiol.*, vol. x.); "On Disturbances of Sensation, with especial reference to the Pains of Visceral Disease" (Part I., *Brain*, 1893, Part II., *Brain*, 1894).

CONWY LLOYD MORGAN,

F.G.S. Professor of Biology and Geology, University College, Bristol, and Principal of the same College. Correspondent of the Academy of Sciences of Philadelphia and New York. As a geologist, Prof. Lloyd Morgan has done a considerable amount of original work in Pembrokeshire and the Bristol district. His chief claim to scientific distinction, however, rests upon his careful experiments and observations on the habits, instincts, and intelligence of Animals, and his critical study of the true biological significance of the facts and their bearing upon some of the most fundamental problems of Organic Evolution. The three volumes which he has published on these subjects are of very high merit, and, in the opinion of the signers of this certificate, place their author in the first rank as a philosophical biologist. Author of the following memoirs:—(1) "Animal Life and Intelligence," 1890; (2) "An Introduction to Comparative Psychology," 1894; (3) "Habit and Instinct," 1896; and of the following geological papers:—"On the Pebidian Volcanic Series of St. David's" (*Quart. Journ. Geol. Soc.*, vol. xlvi., 1890); "On the S.W. Extension of the Clifton Fault" (*ibid.*, vol. xli., 1885); and twelve geological papers in the *Proc. Bristol Nat. Soc.*, 1884–90, and other local scientific periodicals.

CLEMENT REID,

F.G.S., F.L.S. Geologist in the Geological Survey of England and Wales, and has served on the Staff since 1874. Awarded the Murchison Fund by the Council of the Geological Society in 1886. Has been Secretary and Recorder to the Geological Section of the British Association. Has added largely to our knowledge of the Lower Tertiary formations of the Isle of Wight and Dorset, the Pliocene deposits of Norfolk and the North Downs (including the fauna and flora of the Cromer Forest Bed), and the Glacial Phenomena of Norfolk and Sussex. To aid his researches he has made a special study of recent and fossil seeds (a subject previously much neglected), whereby much light has been thrown on the climatic conditions of later Tertiary times, and on the origin of the British flora. Author of Geological Survey memoirs on "Geology of the Country around Cromer," 1882; "Geology of Holderness," 1885; "Pliocene Deposits of Britain," 1890, and revised Tertiary portion of "Geology of Isle of Wight," 2nd ed., 1889. Also author of many original papers, including "Dust and Soils" (*Geol. Mag.*, 1884); "Norfolk Amber" (*Trans. Norf. Nat. Soc.*, 1884); "Origin of Dry Chalk Valleys" (*Quart. Journ. Geol. Soc.*, 1887); "Geological History of the Recent Flora of Britain" (*Ann. Botany*, 1888); "Pleistocene Deposits of Sussex Coast" (*Quart. Journ. Geol. Soc.*, 1892); "Natural History of Isolated Ponds" (*Trans. Norf. Nat. Soc.*, 1892); "Desert or Steppe Conditions in Britain" (*Nat. Science*, 1893); "Eocene Deposits of Dorset" (*Quart. Journ. Geol. Soc.*, 1896); "Report on Relation of Palæolithic Man to the Glacial Epoch" (Hoxne Excavation) (Brit. Assoc., 1896).

HENRY SELBY HELE SHAW,

LL.D. (St. And.), Engineer. Mem. Inst. C.E., Mem. Inst. M.E., F. R. Met. Soc., Harrison Professor of Engineering, University College, Liverpool. Senior Whitworth Scholar, 1876, and Miller Scholar of the Inst C.E. Distinguished for his acquaintance with Engineering and Mechanical Science. Inventor of integrating and power transmitting mechanism. Was the first Professor of Engineering at Bristol and afterwards at Liverpool. At Liverpool he organised the School of Engineering and designed and supervised the equipment of the Walker Engineering Laboratories, in which there are now nearly 100 day students under instruction. Author of "Theory of Continuous Calculating Machines" (*Phil. Trans.*, 1884); also of the following communications:—"On Small Motive Power" (Inst. Civil Engineers, 1880); "On the Measurement of Velocity for Engineering Purposes" (*ibid.*, 1882); "On Mechanical Integrators" (*ibid.*, 1885) (awarded the Watt Gold Medal and Telford premium); "Sphere and Roller Mechanism," jointly with Mr. E. Shaw (Brit. Assoc., 1886); "First Report on Graphical Methods in Mechanical Science" (*ibid.*, 1891); "Second Report on the Development of Graphical Methods in Mechanical Science" (*ibid.*, 1892); "Third Report on Graphical Methods" (*ibid.*, 1893); "Experimental Investigation of the Motion of a Thin Film of Viscous Fluid," appendix by Sir G. G. Stokes, F.R.S. (*ibid.*, 1898); "A New Instrument for Drawing Envelopes, and its Application to the Teeth of Wheels, and for other Purposes" (*ibid.*, 1898); "Rolling Contact of Bodies" (Roy. Inst., 1887, Friday evening Discourse); "The Motion of a Perfect Fluid" (*ibid.*, 1899, Friday evening Discourse); "Experiments on the Nature of Surface Resistance in Pipes and on Ships" (Inst. Naval Architects, 1897); "Investigation of the Nature of Surface Resistance of Water, and of Stream Line Motion under Certain Experimental Conditions" (*ibid.*, 1898) (awarded the Gold Medal of the Institution); "Experimental Marine Engine and Alternative-centre Testing Machine in the Walker Engineering Laboratory" (Inst. Mechanical Engineers, 1891); and other papers to the Society of Arts, Physical Society, and Societies in Bristol, Liverpool and elsewhere.

ERNEST HENRY STARLING,

M.D., F.R.C.P., Joint Lecturer on Physiology, Guy's Hospital, Lecturer on Physiology, London School of Medicine for Women. Distinguished as a Physiologist. Author of the following: "Electromotive Phenomena of the Mammalian Heart" (*Proc. Roy. Soc.*, vol. l., and *Internat. Journ. of Anat. and Physiol.*, vol. ix., with W. M. Bayliss); "Innervation of Mammalian Heart" (*Journ. of Physiol.*, vol. xiii., with W. M. Bayliss); "Fate of Peptone in Blood" (*Proc. Physiol. Congress, Liège*, 1892); "Physiology of Lymph Secretion" (*Journ. of Physiol.*, vol. xiv.); "Absorption and Secretion in Serous Cavities" (with A. H. Tubby, *ibid.*, vol. xvi.); "Nervous and Capillary Pressures" (with W. M. Bayliss, *ibid.*, vol. xvi.); "Mechanical Factors in Lymph Production" (*ibid.*, vol. xvi.);

"Action of Lymphagogues" (*ibid.*, vol. xvii.); "Vaso-Constrictors of Portal Vein" (with W. M. Bayliss, *ibid.*, vol. xvii.); "Intraventricular and Aortic Pressure Curves by a New Method" (with W. M. Bayliss, *Internat. Journ. of Anat. and Physiol.*, vol. xi.); "Osmotic Pressures and Physiol. Problems" (*Science Progress*, 1896); "Absorption from Pleural Cavities" (with J. B. Leathes, *Journ. of Physiol.*, vol. xviii.); "Production of Pleural Effusion" (*Journ. of Pathol.*, vol. iv.); "Absorption from Connective Tissue Spaces" (*Journ. of Physiol.*, vol. xix.); "Ligature of Portal Lymphatics and Injection of Peptone" (*ibid.*, vol. xix.); "Absorption of Indigo Carmine from Peritoneal Cavity" (*Proc. Physiol. Soc.*, 1898, Arris and Gale Lectures); "Physiol. of Lymph Formation," 1894; "Causation of Dropsy," 1896; "Pathol. of Heart Disease," 1897. Author of "Elements of Human Physiol.," 3rd edit., 1897; of the following articles in Schäfer's Text-book of Physiology: "Formation and Absorption of Lymph"; "Secretion of Urine"; "Special Muscular Mechanisms of Respiration, Alimentation, Micturition," &c. Editor of Metschnikoff's Lectures on Pathology of Inflammation. Joint Editor of the Collected Works of L. C. Wooldridge.

HENRY WILLIAM LLOYD TANNER,

M.A. (Oxon.), F.R.A.S., A.R.S.M., Professor of Mathematics and Astronomy in the University College of South Wales and Monmouthshire, Member (and sometime Member of Council) of the London Math. Soc. Distinguished as a mathematical investigator, author of several papers on "Differential Equations" (*Proc. Lond. Math. Soc.*, vols. vii., viii., ix., x., xi.; *Quart. Journ. Math.*, vol. xvi.; *Mess. Math.*, vols. v., vi., vii.); "On Determinants of $n$ Dimensions" (*Proc. Lond. Math. Soc.*, vol. x.); "On the Coordinates of a Plane Curve in Space" (*ibid.*, vol. xiii.); "On the Function $(ax + b)(cx + d)$" (*Mess. Math.*, vol. ix.); "On Spherical Trigonometry" (*ibid.*, vol. xiv.); "Sturm's Theorem" (*ibid.*, vol. xviii.); "Solution of $(a, b, \ldots, c) = (a^p, b^p, \ldots, c^p)$" (*ibid.*, vol. xix.); "Arbogast's Rule" (*ibid.*, vol. xx.); "Square Roots of Unity for a Prime Modulus" (*ibid.*, xxi.); "Quinquisection of $x^p - 1$" (*Proc. Lond. Math. Soc.*, vol. xviii.); "Cyclotomic Functions" (*ibid.*, vol. xx.); "Approximate Evolution" (*ibid.*, vol. xxiii.); "Complex Primes formed with Fifth Roots of Unity" (*ibid.*, vol. xxiv.).

RICHARD THRELFALL,

M.A., late Professor of Experimental Physics, University of Sydney, New South Wales. Author of the following papers: "On the Electrical Properties of Pure Sulphur" (in conjunction with Mr. Brearly, *Phil. Trans.*, 1896); "On the Conversion of Energy in Dielectrics" (*Physical Review*, vol. iv.); "On the Behaviour of Oxygen at Low Pressures" (*Phil. Mag.*, 1897); "On the Scattering of Light by Metallic Particles" (*ibid.*, vol. xxxviii.); "On an Approximate Method for Finding the Forces on Magnetic Circuits" (*ibid.*); "On the Electrical Properties of Pure Nitrogen" (*ibid.*, vol. xxxv.); "On the Elastic Properties of Quartz Threads" (*ibid.*, vol. xxx.); "On the Measurement of High Specific Resistances" (*ibid.*, vol. xxviii.); "On the Clark Cell as a Source of Small Constant Currents" (with Mr. Pollock, *ibid.*); "On the Specific Heat of the Vapours of Acetic Acid and Nitrogen Tetroxide" (*ibid.*, vol. xxiii.); "On the Theory of Explosives" (*ibid.*, vol. xxi.); "On the Velocity of Transmission through Sea Water of Disturbances of Large Amplitude caused by Explosives" (*Proc. Roy. Soc.*, vol. xlvi.); "On the Effect produced by the Passage of an Electric Discharge through Nitrogen" (with Prof. J. J. Thomson, *ibid.*, 1886); "Some Experiments on the Production of Ozone" (with Prof. J. J. Thomson, *ibid.*); "Laboratory Arts" (Macmillan and Co., 1898). Introducer of improvements in the Microtome.

ALFRED E. TUTTON,

F.C.S., Associate Royal College of Science. Member Mineral. Soc. Inspector, Science and Art Department. Has made discoveries in crystallography, and has invented instruments for research in this branch of science. Is the author of the following papers: "Connection between Atomic Weight of Contained Metals and the Magnitude of the Angles of Crystals of Isomorphous Series. A Study of the Potassium, Rubidium, and Caesium Salts of the Series $R_2M(SO_4)_2, 6H_2O$" (*Journ. Chem. Soc.*, 1893, p. 337: and *Zeits. für Kryst.*, vol. xxi., p. 491); "An Instrument for Grinding Section-Plates and Prisms of Crystals of Artificial Preparations Accurately in the Desired Directions" (*Phil. Trans.*, 1894A, p. 887, and *Zeits. für Kryst.*, vol. xxiv., p. 433); "An Instrument for Producing Monochromatic Light of any Desired Wave-Length, and its use in the Investigation of the Optical Properties of Crystals" (*Phil. Trans.* 1894A, p. 913; and *Zeits. für Kryst.*, vol. xxiv., p. 455); "Connection between the Atomic Weight of Contained Metals, and the Crystallographical Characters of Isomorphous Salts. The Volume and Optical Relationships of the Potassium, Rubidium and Caesium Salts of the Series $R_2M(SO_4)_2, H_2O$" (*Journ. Chem. Soc.*, 1896, p. 344; and *Zeits. fur Kryst.*, vol. xxvii., p, 113); "Comparison of the Results of the Investigations of the Simple and Double Sulphates, and General Deductions concerning the Influence of Atomic Weight on Crystal Character" (*Journ. Chem. Soc.*, 1896, p. 495; and *Zeits. für Kryst.*, vol. xxvii., p. 252); "Connection between the Crystallographical Characters of Isomorphous Salts and the Atomic Weight of the Metals Contained. A Study of the Normal Selenates of Potassium, Rubidium, Caesium" (*Journ. Chem. Soc.*, 1897, p. 846; and *Zeits. für Kryst.*): and of various papers in the *Journal* of the Chemical Society and other journals. Author of the following Memoirs, in conjunction with Prof. Thorpe: "Phosphorus Tetroxide" (*Journ. Chem. Soc.*, 1886, p. 833); "Phosphorus Oxide, Part I." (*ibid.*, 1890, p. 545); "Phosphorus Oxide, Part II." (*ibid.*, 1891, p. 1019); "Ueber Phosphoroxysulfid" (*Zeits. Anorg. Chem.*, 1892–5).

BERTRAM COGHILL ALLEN WINDLE,

M.D., M.A., D.Sc. (Dublin). Professor of Anatomy, Queen's College, Birmingham. Has devoted himself to the study of Human and Comparative Anatomy and Morphology; and has published the following works and papers on these and kindred subjects:—(1) "On the Embryology of the Short Muscles of the Manus and Pes of the Dog" (*Proc. R. Irish Acad.*, vol. iii.); (2) "The Embryology of the Short Muscles of the Human Hand" (*Trans. R. Irish Acad.*, xxviii.); (3) "On the Pectoral Group of Muscles" (*ibid.*, xxix.); (4) "Teratological Evidence as to the Heredity of Acquired Characters" (*Journ. Linn. Soc.*, xxiii.); (5) "On the Anatomy of *Hydromys chrysogaster*" (*Proc. Zool. Soc.*, 1887); (6) "On some Cranial and Dental Characters of the Domestic Dog" (in conjunction with Mr. Humphrys) (*ibid.*, 1890); (7) "On an Abnormal Arrangement of the Large Intestine" (*Journ. of Anat.*, vol. xx.); (8) "On Primary Sarcoma of the Kidney" (*ibid.*, xix.); (9) "On the Condition of the Brain in a case of Motor Aphasia with Deafness" (*ibid.*, new series, i.); (10) "Man's Lost Incisors" (*ibid.*, i.); (11) "Anomalies of Muscles and Nerves" (*ibid.*); (12) "Two Rare Tumours connected with the teeth" (*ibid.*); (13) "The Myology of *Erethizon epixanthus*" (*ibid.*, ii.); (14) "On the Arteries forming the Circle of Willis" (*ibid.*); (15) "On a Teratoma from the Sphenoid of a Calf" (*ibid.*); (16) "On the Myology of *Procyon cancrivorus*, and others of the Ursidæ" (*ibid.*, iii.); (17) "On the Origin of Double Monstrosities" (*ibid.*); (18) "On the Flexors of the Digits of the Hand" (*ibid.*, iv.); (19) "Ununited Epiphyses" (*ibid.*); (20) "On the Stylo-auricularis Muscle and Ligament" (*ibid.*, v.); (21) "On the Occurrence of an Additional Phalanx in the Human Pollex" (*ibid.*, vi.); (22) "On Identical Malformations in Twins" (*ibid.*); (23) "Sacculation of the Human Stomach" (*Proc. Birmingham Philos. Soc.*, v.); (24) "Myology of *Midas rosalia*" (*ibid.*); (25) "Myology of *Hapale Jacchus*" (*ibid.*); (26) "The Adductor Muscles of the Hand" (*ibid.*); (27) "The Extensors of the Manus in the Ape" (*ibid.*, vi.); (28) "On Congenital Malformation and Heredity" (*ibid.*); (29) "Researches on the Maturation of the Ovum" (*ibid.*); (30) "Certain Malformations in Fishes" (*ibid.*); (31) "Investigations in Artificial Teratogeny" (*ibid.*, vii.); "Extra Cusps on Human Teeth" (*Anat. Anzeiger*, vol. ii.); (33) "Congenital Deficiency of Thumb" (*ibid.*, iii.); (34) "Malformations of the Face" (*ibid.*, iv.); (35) "Musculus sternalis" (*ibid.*); (36) "The Human Skull" (*Birmingham Med. Review*, vol. xviii.); (37) "Hermaphroditism" (*ibid.*, xx.); (38) "Development of Intermaxillary Bone" (*ibid.*, xxv.); (39) "A Manual of Surface-Anatomy" (London, H. K. Lewis, 1888); (40) "The Proportions of the Human Body" (London: Baillière, Tindall, and Cox, 1892).

*Supplementary Certificate.*—"On the Myology of the Pneucephalous Fœtus" (*Journ. of Anat. and Physiol.*, vol. xxvii.,

p. 348); "On Certain Early Malformations of the Embryo" (*ibid.*, p. 436); "On some Conditions related to Double Monstrosity" (*ibid.*, vol. xviii., p. 25); "The Effects of Electricity and Magnetism on Development" (*ibid.*, vol. xxix., p. 346); "On the Myology of *Dolichotis Patagonica* and *Dasyprocta Isthmica*" (*ibid.*, vol. xxxi., p. 343); "On some Points in Comparative Myological Nomenclature" (*ibid.*, vol. xxxi., p. 522); "On the Anatomy of *Macropus Rufus*" (*ibid.*, vol. xxxii., p. 119); "On a Specimen of Bifid Clitoris" (*Proc. Anat. Soc. Gt. Brit.*, 1893, vol. xxii.); "On the Cusps of the Aortic Pulmonary Orifices" (*ibid.*, 1895, vol. iv.); "On the Double Malformations amongst Fishes" (*Proc. Zool. Soc.*, 1895, p. 423); "On the Myology of the Terrestrial Carnivora.—Part I., Muscles of the Head, Neck and Fore-Limb" (*ibid.*, 1897, p. 370); "On the Physical Characters of the Boys at King Edward's Schools, Birmingham, and at certain other Public Schools" (*Proc. Birm. Phil. Soc.*, 1892, 216); "On the Physical Characters of a Group of Birmingham Pupil Teachers" (*ibid.*, 1895, p. 97); "Note on a Roman Pottery near Mancetter" (*Proc. Soc. Antiq.*, vol. xvi., p. 404); "On the Prehistoric Implements of Warwickshire and Worcestershire" (*Birm. Arch. Soc. Proc.*, 1897); "Life in Early Britain: being an Account of the Early Inhabitants of this Island and the Memorials which they have left behind them" (London: D. Nutt, 1897).

## *WORK OF THE SMITHSONIAN INSTITUTION IN 1897–8.*

THE report of Prof. S. P. Langley, Secretary of the Smithsonian Institution, upon the operations of the Institution for the year ending June 30, 1898, reached us a few weeks ago. It refers to the work of the U.S. National Museum, the Bureau of American Ethnology, the International Exchanges, the National Zoological Park, and the Astrophysical Observatory, all of which are under the direction of the Institution.

Map showing distribution of Correspondents of the Smithsonian International Exchange Service.

The promotion of original research has always been one of the principal functions of the Institution. Investigations in the anthropological, biological and geological divisions of science have been extensively carried on through the departments of the National Museum, and in the Bureau of American Ethnology there have also been special inquiries into Indian customs and languages. These lines of research being well represented by its bureaus, it has remained for the Institution proper to devote its energies more especially to some of the physical sciences.

Prof. Langley has carried on researches in the solar spectrum, which, by the active assistance of Mr. C. G. Abbot, have produced important results shortly to be published. He has not wholly discontinued the studies which he has made in regard to aërodromic experiments, and it is perhaps not improper that he should state that these have attracted the attention of other departments so far that during the war with Spain a commission was directed by the Secretaries of War and the Navy to inquire into them with a view of their possible utility in war.

In connection with the Hodgkins fund, several grants have been made for scientific investigations. Mr. A. Lawrence Rotch, of the Blue Hill Meteorological Observatory, Readville, Mass., has received grants for experiments with automatic kites, for determining, by means of self-recording instruments, meteorological data in atmospheric strata inaccessible except by some mechanical method of exploring the atmosphere.

A grant of 500 dollars has been made to Prof. William Hallock, of Columbia University, for an investigation having for its object the complete analysis of a particle of air under the influence of articulate sounds.

A final grant of 250 dollars has been made to Drs. Lummer and Pringsheim, of the Physical Institute of the University of Berlin. The investigation begun by them, in 1893, to determine the ratio of the specific heats, at constant pressure and volume, for air, oxygen, carbon dioxide and hydrogen has now so far progressed that the memoir submitted by Drs. Lummer and Pringsheim, noting the results already attained by them, has been published by the Institution in the Smithsonian "Contributions to Knowledge."

An additional grant has been made to Mr. E. C. C. Baly, of University College, London, to enable him to continue his research upon the decomposition of the atmosphere by electricity and upon the ozonising of mercury.

A grant of 250 dollars has been made to Prof. Arthur G. Webster, of Clark University, Worcester, Mass., for the continuation of a research on the properties of air in connection with the propagation of sound, special effort being directed to the securing of data relating to the influence of the viscosity of air on expiring or vanishing sounds. An instrument devised by Prof. Webster for use in this investigation gives the physical measure of sound, not only when constant, but when rapidly varying. It is expected that this research will furnish results of high practical value in connection with the question of the acoustics of auditoriums, and will contribute information upon points that have not heretofore been satisfactorily investigated.

The operations of the International Exchange Service continue to extend. In 1887 this branch of the Institution sent out 71 tons of documents, and had 2165 correspondents in the United States and 7396 foreign correspondents; during the year covered by the present report it transmitted 151 tons, and had 6915 correspondents at home and 22,543 abroad distributed among 93 countries.

Of the total number—29,458—of correspondents, 12,698 are libraries and 16,760 are individuals. There is no part of the Smithsonian Institution which more efficiently carries out the large purpose of its founder, to diffuse knowledge among men, and it is through this, as much as through any other branch, that its name is known throughout the world.

Appended to the report is a map of the world, a reduction of which accompanies this summary, showing the distribution of the correspondents of the Exchange Service.

## NOTES.

THE Bakerian Lecture of the Royal Society will be delivered next Thursday, May 18. The subject is "The Crystalline Structure of Metals," by Prof. Ewing, F.R.S., and Mr. W. Rosenhain.

A DINNER of the Royal Institute of Public Health will be held at the Hotel Cecil on June 7 to meet Lord Lister, P.R.S., who will be presented with the Harben gold medal, and other distinguished guests, who will receive the Honorary Fellowship of the Institute.

THE Council of the Royal Geographical Society has awarded the founder's gold medal for this year to Captain Binger, who in the years 1887-89 carried out an extensive series of explorations in the vast area included in the bend of the Niger. The patron's medal has been awarded to M. Foureau for his explorations in the Sahara during the last twelve years. The Murchison award has been given to Mr. Albert Armitage for his valuable scientific observations made during the Jackson-Harmsworth Arctic expeditions; the Gill memorial to the Hon. David Carnegie for his journey across the Western Australian desert; the Cuthbert Peek grant to Dr. Nathorst for his important scientific exploration of the Spitsbergen Islands and the seas between Spitsbergen and Greenland; the Back grant to Captain Sykes for his three journeys through Persia, during which he has made important corrections and additions to the map of that country, and done much to clear up the geography of Marco Polo. These honours will be awarded at the anniversary meeting of the Society on June 5, and at the same time the American Ambassador will present to Sir John Murray the gold medal of the American Geographical Society for his contributions to scientific geography.

THE Duke of the Abruzzi has left Rome for Turin, whence he will start on his journey to the Arctic regions.

A LECTURE on "London Fog and Smoke," delivered by the Hon. F. A. Rollo Russell at the Building Trades Exhibition, is published in the *Public Health Engineer* of May 4. From the tables given it appears that during the five months November 1898 to March of the present year, London had rather less than half the amount of sunshine of inland stations, and little more than one-third of the sunshine of the stations on the south coast —all the stations with which comparison was made being within a hundred miles of the metropolis. Mr. Russell thinks that drastic measures should be taken to reduce the smoke nuisance from which London suffers. Apparatus conforming to certain stipulations are now enforced upon owners of house property by the local authorities, and there is no reason why similar rules for the public advantage should not be imposed upon builders and owners in relation to the consumption of fuel. Mr. Russell remarks in conclusion: "If any serious difficulty presents itself in bringing into practice the suggested taxes and remissions, the same principle of compulsion which is adopted for drainage, sanitary appliances, and building materials, might be put into force for the sake of atmospheric purity. There is nothing more important for the welfare of the race than good air, and we know that largely owing to the want of it, the populations of the central parts of our big towns decline and perish, unless continually recruited from the country. And thousands are ever flocking from country to town. Only by a return to the countiy, or by great improvements in the conditions of urban life, can the nation maintain its prosperity."

THE annual conversazione of the Society of Arts will take place at the Natural History Museum, South Kensington, on Tuesday, June 20.

NEWS has reached us of the death of Mr. Mariano de la Bárcena, director of the Central Meteorological Observatory, Mexico.

THE fourth annual congress of the South-Eastern Union of Scientific Societies will be held in the Mathematical School, Rochester, on May 25-27, under the presidency of Prof. G. S. Boulger.

ON Tuesday next, May 16, Prof. W. J. Sollas, F.R.S., will deliver the first of a course of three lectures at the Royal Institution on "Recent Advances in Geology"; and on Thursday, May 25, Prof. L. C. Miall, F.R.S., will begin a course of two lectures on "Water Weeds."

REFERRING to the recent celebration of the centenary of Spallanzani, the Rome correspondent of the *Lancet* says:—Nature study, up to its most refined developments in clinical observation and research, was largely represented at Scandiano, where the great naturalist, physiologist, and scholar, Lazzaro Spallanzani, died one hundred years ago. Prof. Todaro (Rome), Prof. Mosso (Turin), Prof. Bertolini (Bologna), Prof. Pavesi (Pavia), and many others hardly less distinguished, met to do honour to his memory and to inaugurate the *gabinetti scientifici* erected in the neighbouring Reggio Emilia to continue and commemorate his work. The Minister of Public Instruction was represented by Moleschott's successor in the Roman chair of Physiology, Prof. Luciani, whose speech at the tomb of the hero of the day was in all respects worthy of his reputation.

THE first statutory general meeting of the National Association for the Prevention of Consumption and other Forms of Tuberculosis, of which the Prince of Wales is president, was held on Thursday last. The Association has made much progress, no less than 1252 members having been enrolled. The members of the Council include Sir W. Broadbent, Sir J. Blyth, Sir G. T. Brown, Sir J. Crichton Browne, Sir J. T. Brunner, M.P., Sir A. Christison, Sir Ernest Clarke, Prof. Corfield, Sir R. G. Wyndham Herbert, Prof. McFadyean, Sir H. Maxwell, and Sir Frederick Wills. Dr. Clifford Allbutt, in moving a vote of thanks to the organising committee, said that since the last generation England had been losing the leading position which she had attained in preventive medicine, and he suggested the advisability of chairs of comparative pathology being established. Dr. Church, the president of the Royal College of Physicians, in seconding the motion, pointed out that the movement against tuberculosis was not a matter in which the medical profession alone were interested, or in which they should take a leading part.

THE short paper on "Aetheric Telegraphy" read before the Society of Arts on May 3, by Mr. W. H. Preece, C.B., F.R.S., and printed in the current number of the Society's *Journal*, constitutes an instructive statement as to what has been accomplished in wireless telegraphy by Mr. Marconi and before him, and what can be expected from it in the near future. As to the practical value of wireless telegraphy at present, Mr. Preece remarks: "There can be no question of the commercial value of the system for lightships, isolated lighthouses, shipping generally, and for [naval and military purposes, but for commercial uses, such as telegraphic communication with France, the system is at present nowhere. A single cable to France could transmit 2500 words a minute without any difficulty. A single Marconi circuit could not transmit more than twenty words a minute."

IN connection with the subject of electrical signalling without intervening wires, an interesting letter by Prof. D. E. Hughes appears in the current number of the *Electrician*. Prof. Hughes describes experiments made by him in 1879, and witnessed by several distinguished Fellows of the Royal Society, on

phenomena produced by ether waves, and the action of the waves on a microphonic coherer across intervening space. Electric waves as such were then unknown to science, so that Prof. Hughes apparently anticipated Hertz's brilliant discoveries. He also conducted experiments on wireless signalling on a considerable scale. In 1879, 1880, and 1888, he demonstrated to several eminent men of science his experiments upon aerial transmission of signals by means of the extra current produced from a small coil, and received upon a semi-metallic microphone, the results being heard upon a telephone in connection with the receiving microphone. The transmitter and receiver were in different rooms, about 60 feet apart, but signals were also received up to a distance of 500 yards, and an attempt was made to signal between houses a mile apart. Prof. Hughes considered that the results were produced by aërial electric waves; and it was because he was unable to demonstrate the actual existence of these waves that his investigations were never published.

A GOOD instance of the manner in which "sea-serpent" myths originate is afforded by certain paragraphs which have recently appeared in the Australian papers. In its issue of February 23 the Melbourne *Argus* announced the discovery at Suwanaw Island, by the officer of a local steamer, of the remains of a sea-monster that had been stranded there some two months previously. The creature was said to be in such a bad condition that collecting its remains was a most trying task; but "two heads, the two backbones, and part of the ribs" were secured. It was stated that there was "but one body, which had a double spine, and two distinct heads"; while the approximate weight of the animal was estimated at not less than 70 tons, and its length fully 60 feet! In the issue of the following day the skulls were said to be about 3 feet long, and to carry a pair of tusks at the tip of the lower jaw. On March 2 the same paper published an announcement that Mr. E. Waite, of the Australian Museum, had identified the remains as those of a "Zithoid"—obviously a misprint for "Ziphioid." It would thus appear that the alleged double-headed monster of 70 tons weight and 60 feet length was based on two carcases of one of the species of Beaked Whales which are of such comparatively common occurrence on the Australian coasts, and the largest of which is not known to exceed 30 feet in length!

AT the last meeting of the Anatomical Society of Great Britain and Ireland, Dr. Elliot Smith settled a point in the comparative morphology of the brain, which at one time was the subject of a heated controversy between Huxley and Owen. In 1861, it may be remembered, Owen maintained that the *calcar avis* and the calcarine fissure which causes it, were characters peculiar to the brain of man; a statement which Huxley showed to be untrue, the formations being well-marked in all Primate brains. Dr. Elliot Smith has reached the further generalisation that the *calcar avis* is a character shown by all mammalian brains, with the possible exception of the Prototherian. He identifies, and the reasons for this identification do not seem capable of refutation, the calcarine fissure of the Primate brain with the splenial fissure of the brain of other mammals. This generalisation will materially assist in homologising the Primate and Unguiculate *pallium*.

IN a paper on "The Western Interior Coal-field of America," by Mr. H. Foster Bain, read at a recent meeting of the North of England Institute of Mining and Mechanical Engineers, the author refers to the estimated area of the coal-fields of the United States as being from 200,000 to 300,000 square miles. In this estimate tracts of Mesozoic as well as Carboniferous coal-bearing strata are included. The Western Interior coal-field occupies a portion of the western half of the Mississippi valley, and is the third in point of production in the United States. Its yield in 1897 was over thirteen million tons. The strata are all grouped as Carboniferous, although some of the higher portions have been regarded as Permo-Carboniferous. Correlations based on fossil evidence are said to be of doubtful value, as the common fossil of the upper strata occur well down in the lower beds. With regard to the coal-seams, all grades from semi-anthracite to free-burning non-coking coal occur, including gas-coal, cannel, and coking-coals.

THE detailed petrographical description of some rock-specimens from Ceylon forms the subject of an interesting paper, by Herr Max Diersche, in the *Jahrbüch der k. k. geol. Reichsanstalt*, Bd. xlviii. Hft. 2 (Wien, 1898). The work is based on material collected by Prof. F. Zirkel during the winter of 1894, and the rock-types described include normal granulite, pyroxene-granulite, gneiss, granite, limestone, and quartzite. An interesting section is devoted to a description of the plumbago of Ragedara and its inclusions. The author remarks on the peculiar occurrence of the graphite at this locality in the form of ramifying veins of varying thickness, sharply marked off at the margins from the surrounding matrix of granulite and pyroxene-granulite. The peculiar mineral and rock inclusions which occur in the graphite veins are dealt with at length, and the paper concludes with a brief discussion of some of the theories that have been brought forward to account for the origin of the graphite. This number of the *Jahrbüch* contains also a geological description of the southern part of the Karwendel Alps, by Herrn Ampferer and Hammer. The region comprised is situated immediately to the north of the Inn valley in the neighbourhood of Innsbruck, and is one which, from its complex relations of structure and facies, offers many difficult problems for geological elucidation. But the authors, with limited time at their disposal, have dealt in a comprehensive manner with the stratigraphy and tectonic relations of this complicated area; and their paper, illustrated by numerous diagrams and accompanied by a coloured geological map, should prove of value to students of Alpine geology.

ANOTHER important contribution to our knowledge of the geology of the Alps appears in the *Verhandlungen* of the above institution (December 1898), where Dr. E. Shellwien records the discovery of a typical marine Permo-Carboniferous fauna in the neighbourhood of Neumarktl, in the Eastern Alps. This occurs at the horizon of the light *Fusulina*-limestone of the Carnic Alps, and there is evidence that in this region there has been uninterrupted deposition from the middle of the Upper Carboniferous into the Lower Permian. The author is led to regard this Permo-Carboniferous limestone as the equivalent of the Cusel beds of Germany. The fauna includes new and interesting forms, and among the Brachiopoda some remarkable types are found to occur. Besides representatives of the genera *Scacchinella* and *Meekella*, a new genus, *Tegulifera*, is present in abundance. It is characterised by a peculiar mode of growth of the larger valve, the lateral margins of which overlap the smaller valve, and, by their continued growth, ultimately envelop the latter completely. The discovery of this comparatively rich fauna corroborates in the fullest manner the views for some time held by Stache regarding the true age of the upper *Fusulina*-limestone stage in the Carnic and Julian Alps.

WE have received a copy of the Second Annual Report of the Geological Commission of the Cape of Good Hope for 1897, and published in 1898. This contains a first instalment of the geological map, neatly printed in colours, and including great part of the Colony eastwards to Cape Infanta and Ladismith, and northwards to Cape Columbine and Laingsburg. The map, which is on a scale of about an inch to 12 miles, is the work of Messrs. A. W. Rogers and E. H. L. Schwarz; and it is accom-

panied by sections showing the flexured structure of the country. A well-deserved tribute is paid to the previous labours of Andrew Geddes Bain and E. J. Dunn. The oldest rocks, known as the Malmesbury Beds, comprise non-fossiliferous slates, mica-schists and quartzites, with intrusive granite. A great unconformity exists between these rocks and the overlying Table Mountain Sandstone. That series again is non-fossiliferous, but it is succeeded by the Bokkeveld Beds, shales and sandstones which yield genera characteristic of the Devonian period. The overlying Witteberg Beds, mainly quartzites, have yielded but a few obscure plant-remains; while still higher in the sequence comes the Dwyka Conglomerate, which may be of subaërial origin; and above it there is a series of shales and sandstones, known as the Ecca Beds, which have yielded occasional plant-remains. This great series overlying the Bokkeveld Beds is usually regarded as of Carboniferous age. Attention is given in the Report to the superficial deposits, and to the economic products of the regions examined. The work of the Survey is superintended by Prof. G. S. Corstorphine.

THE Meteorological Section of the Hydrographical Committee of St. Petersburg has published, as a supplement to vol. xix. of the *Hydrographical Journal*, a useful collection of tables referring to lighthouses and stations on the shores of the Black Sea and Sea of Azov, and of the Caspian, Baltic and White Seas. The observations were made in the years 1890–6, and give for each month and year particulars relating to the level of the water, the direction and velocity of wind, and the temperature of the sea surface. The text also contains details of the various stations, the times of observation, &c.

IN the *Verhandlungen* for 1898 of the Natural History Society for the Prussian Rhineland, &c., Dr. Geisenheyner commences an exhaustive account of the Rhenish Polypodiaceæ. The present instalment is entirely devoted to the three species *Blechnum spicant*, *Scolopendrium vulgare*, and *Ceterach officinarum*; numerous forms, varieties, and sports being described in great detail.

THE first and second Hefts of vol. xxvii. of Engler's *Botanische Jahrbücher* are chiefly devoted to instalments, by various authors, of the editor's contributions to the Flora of Africa. There are, in addition, papers by Dietel and Neger on the Uredineæ of Chile; by Pilger, on South American grasses; and by Ule, on the Sphagnaceæ of Brazil.

MR. A. H. TROW reprints from the *Annals of Botany* a paper containing an elaborate account of researches on a Welsh variety of *Achlya americana*, undertaken with the special object of determining the nature of the chromosome-like body in the centre of the nucleus. His conclusion is that the nucleus is bounded by a nuclear membrane, and possesses a central body of spongy texture, which contains chromatin and nucleolar matter, but is neither a nucleole nor a chromosome. He thinks it probable that the reducing divisions in the different groups of plants are not all homologous. There is a true homology in the Muscineæ, Vascular Cryptogams, and Spermaphytes; while in the Thallophytes there are apparently two types of reducing division which are not homologous.

WE have received (in two parts) an exhaustive account of the indigenous native drugs of Australia, by Mr. J. H. Maiden, Government Botanist, issued by the Department of Agriculture, Sydney. It would appear, from Mr. Maiden's opening remarks, that Queensland is by far the richest of the Australian Colonies in native medicinal plants; but the great majority of these are common to India and the Eastern Archipelago. In New South Wales the number of really useful native drugs is very small. In contrast to the natives of India, the Australian aborigines have but very little knowledge of the medicinal properties of their native plants. In addition to a portion of this same paper, the *Agricultural Gazette of New South Wales* for February 1897 contains also the commencement of a paper by Mr. Maiden on the native food-plants of Australia, as well as a number of others by various writers on the cultivation of fruits and other food-plants, and on the breeding of live-stock, of interest to the colonists.

As already announced, MM. Georges Carré and C. Naud have commenced the publication of a physical and a biological series of brochures, under the title of *Scientia*. The third volume of the biological series, "Les fonctions rénales," by Prof. H. Frenkel, has just been published.

*Pearson's Magazine* for May has an interesting article, by Sir Clements Markham, illustrated by several instructive maps, on the parts of the earth which remain to be explored. The same number contains a short account of Mr. Nikola Tesla's experiments with currents of high potential and high frequency.

THE second part of Mr. M. M. Pattison Muir's "Course of Practical Chemistry" has just been published by Messrs. Longmans, Green, and Co. The first part appeared in 1895, and a third part has yet to be published in order to complete the work. We propose to review Mr. Muir's systematic course of laboratory work when the three volumes are available.

PROF. MAURICE FITZGERALD writes to say that in his article on "The Flight of Birds," in NATURE of April 27, he inadvertently attributed to Lord Kelvin the explanation of the way in which birds may utilise varying air currents for soaring instead of to Lord Rayleigh, who published it in NATURE on April 5, 1883 (vol. xxvii. p. 534).

THE relationships between organic and inorganic chemistry were discussed by Dr. H. N. Stokes in an address recently delivered before the Chemical Society of Washington, and printed in *Science*. Incidentally Dr. Stokes remarks: "The aim of physical chemistry will have been accomplished when it has established a mathematical equation which, by proper substitution, will enable us to predict the nature of every possible chemical system or reaction, and the properties, physical and chemical, of every possible element or compound."

MR. J. G. FRAZER concludes, in the current number of *The Fortnightly Review*, a contribution commenced in the April issue on "The Origin of Totemism." The general explanation of totemism to which the *Intichiuma* ceremonies, which are described in "The Native Tribes of Central Australia," by Messrs. Spencer and Gillen, and discussed in the first part of the paper, seem to point is that it is primarily an organised and co-operative system of magic designed to secure for the members of the community, on the one hand, a plentiful supply of all the commodities of which they stand in need, and, on the other hand, immunity from all the perils and dangers to which man is exposed in his struggle with nature. Such an explanation is shown to be both simple and natural, and in entire conformity with the practical needs as well as the modes of thought of savage man. Referring to the investigations made by Messrs. Spencer and Gillen, Mr. Frazer, while admitting that it may be premature to say their work has finally solved the problem of totemism, says the researches at least point to a solution more complete and satisfactory than any that has hitherto been offered.

PROF. HERDMAN, F.R.S., with the assistance of Mr. Andrew Scott and Mr. James Johnstone, has drawn up in the form of a brochure of eighty-eight pages, the report for 1898 of the Lancashire sea-fisheries laboratory at University College, Liverpool, and the sea-fish hatchery at Piel. The report contains papers by Mr. Andrew Scott on fish-hatching work at Piel, observations on the occurrence and habits of *Leptocephalus*, observations on

the habits and food of young fishes, plankton work and experiments with weighted drift and bottles. Mr. James Johnstone writes on the spawning of the mussel (*Mytilus edulis*); Prof. Herdman on sea-fish hatching, and on oysters and disease: Mr. Charles A. Kohn on occurrence of iron and copper in oysters; Mr. R. S. Ascroft on mussels and mudbanks; and Messrs. F. W. Keeble and F. W. Gamble present a brief report on the physiology of colour-change in *Hippolyte* and other marine crustacea. This is the first complete year of Mr. Scott's work at the Piel hatchery, and of Mr. Johnstone's work at the laboratory. The laboratory attached to the hatchery is open, under certain conditions, to the use of *bona-fide* students and others desirous of prosecuting research. A glance at the above list of papers will show the variety and extent of the investigations that were undertaken last year.

THE scientific activity of the Société de Physique et d'Histoire naturelle de Genève during 1898 is evidenced by the survey of papers published in the *Archives* of the Society, given by Prof. Albert Rilliet in his presidential report just issued. In mathematics and astronomy M. René de Saussure contributed the results of a geometrical study of the movement of fluids, Prof. Gautier computations referring to the return of Tempel's periodic comet, and M. Pidoux observations of an occultation of Antares by the moon. In physics and chemistry M. Dumont gave an account of researches on the magnetic properties of iron and nickel, MM. Dutoit and Friderich described a method of indirectly calculating critical pressure, Prof. Amé Pictet gave an account of further researches on the synthesis of nicotine, and Prof. Soret described his investigations of the causes which produce left- and right-handed crystals in salts active in the crystalline state and inactive in solution. Although no positive results were obtained, the work is important from a statistical point of view. Among the subjects of papers in zoology, physiology, and medicine, were the development of butterflies, by M. Arnold Pictet; and the place of origin of vaso-motor nerves, and effects of currents of high frequency upon the frog, by Dr. Batelli. In botany, a paper by Mlle. Goldfluss on the functions of certain cells was communicated by Prof. Chodat. In physical geology, M. Ed. Sarasin described the records obtained by a limnimeter established at Lucerne during five months in 1897. The records show three distinct periods of oscillation. The results of a detailed inquiry into the constitution of Mont Blanc are given by Prof. Duparc in an important memoir just published by the Society. Finally, mention may be made of a paper by MM. Etienne Ritter and Delebecque on the lakes of the Pyrenees. A number of other papers were read before the Society during 1898, but those here mentioned will be sufficient to show the valuable character of the work accomplished.

THE additions to the Zoological Society's Gardens during the past week include two Mozambique Monkeys (*Cercopithecus pygerythrus*), a Sykes's Monkey (*Cercopithecus albigularis*) from East Africa, presented by Mr. Boyd Alexander; a Macaque Monkey (*Macacus cynomolgus*) from India, presented by Mrs. Herbert Peel; a Slow Loris (*Nycticebus tardigradus*) from Malacca, presented by Mr. W. H. St. Quintin; two Squirrel-like Phalangers (*Petaurus sciureus*, ♂ ♀) from Australia, presented by Mr. A. V. Willcox; four Dormouse Phalangers (*Dromicia nana*) from Tasmania, presented by Dr. McDougall; a Greater Black-backed Gull (*Larus marinus*), a Lesser Black-backed Gull (*Larus fuscus*), European, presented by the Rev. W. B. Tracy; a Drill (*Cynocephalus leucophoeus*), a Kusimanse (*Crossarchus obscurus*), a Pardine Genet (*Genetta pardina*), a Home's Cinixys (*Cynixys homeana*), a Derbian Sternothere (*Sternothoerus derbianus*) from West Africa, a Bell's Cinixys (*Cinixys belliana*) from Tropical Africa, a Common Zebra (*Equus zebra*, ♂) from South Africa, a Grecian Ibex (*Capra oegagrus*, ♂), South-east European, a Two-wattled Cassowary (*Casuarius bicarunculatus*) from the Aroo Islands, deposited; two Larger Tree Ducks (*Dendrocygna major*) from India, purchased; a Mouflon (*Ovis musinon*, ♀) born in the Gardens.

## OUR ASTRONOMICAL COLUMN.

COMET 1899 *a* (SWIFT).—This comet is now well situated for observation in the early morning, and has been frequently seen during the past week. Passing rapidly to the north-west, it will rise earlier every morning, and opportunities will be afforded of obtaining both photographic and visual records of its form and spectrum. The positions predicted by the ephemeris are so nearly correct that there is no possibility of mistaking the comet. As seen on several mornings at the Solar Physics Observatory, South Kensington, it appears to the unaided eye as bright as a star of the fourth magnitude, and, though possessing no tail, is sufficiently unlike a star in appearance to attract notice. With a telescope it is seen to consist of an irregular nucleus about 1′ in diameter, surrounded by a much fainter nebulous mass some 10′ in diameter. Photographs of the spectrum have been obtained showing six bands between D and H, the origins of which have not yet been deduced.

During the week the comet will pass from Pegasus into Lacerta, through a region devoid of conspicuous stars; but on the 17th it will be about 3° west of the second magnitude star o Andromedæ.

The following ephemeris is by Herr H. Kreutz in *Astr. Nach.* (Bd. 149, No. 3556).

*Ephemeris for 12h. Berlin Mean Time.*

TEMPEL'S COMET (1873 II.).—The following ephemeris for this comet is by M. L. Schulhof in *Astr. Nach.* (Bd. 149, No. 3554):—

*Ephemeris for 12h. Paris Mean Time.*

| 1899. | R.A. h. m. s. | Decl. ° ′ ″ | Br. |
|---|---|---|---|
| May 11 | 19 0 46·1 | − 4 15 3 | |
| 12 | 2 25·8 | 4 11 42 | 0·592 |
| 13 | 4 5·2 | 4 8 30 | |
| 14 | 5 44·2 | 4 5 29 | |
| 15 | 7 22·7 | 4 2 38 | |
| 16 | 9 0·9 | 3 59 59 | 0·673 |
| 17 | 10 38·7 | 3 57 31 | |
| 18 | 19 12 16·1 | − 3 55 17 | |

The comet is moving slowly to the north-east, passing from Scutum Sobieski into the southern part of Aquila, being about 10° S.W. of α Aquilæ on the 18th.

A telegram just received from Kiel announces the first observation of this comet during this apparition, by Prof. Perrine at the Lick Observatory. Its position as measured was

R.A. 18h. 52m. 58s. }
Decl. − 4° 32′ 19″ } 1899 May 6, 13h. 40·5m. Lick Mean Time, and it is described as being faint.

The close agreement of these numbers with the computed data given in the ephemeris renders any revision of the latter unnecessary.

## PROGRESS IN THE IRON AND STEEL INDUSTRIES.[1]

THE announcement that Her Majesty the Queen will be graciously pleased to accept the Bessemer Medal for 1899, in commemoration of the progress made in the iron and steel industries during her reign, will be received with enthusiasm throughout the Empire. What the progress has been it will be

[1] Abstract of the presidential address to the Iron and Steel Institute, by Prof. Sir W. Roberts-Austen, K.C.B., D.C.L., F.R.S., delivered before the members of the Institute on May 4.

my privilege to indicate in this Address; for your last President of the century, in bidding it a respectful farewell, must offer the best retrospective tribute he can to the grandest industry in the world's history.

This address will, therefore, be mainly devoted to the consideration of British efforts in connection with iron and steel. I shall hope on another occasion to pay homage to the services rendered in other countries to our branch of metallurgy, but in view of our autumn meeting last year at Stockholm, I cannot proceed further without making a brief reference to Sweden. To her scientific men our debt is great and of long standing, for we have profited by their labours from the eighteenth century until now. We appreciated the interest in our proceedings which was shown by the presence of His Majesty the King and the Royal Princes at our meetings in the Riddarhus. The gracious kindness of His Majesty during the magnificent reception at his palace of Drottningholm will never be forgotten by those of us who were present. The spontaneous warmth of our reception by the Swedish people also touched us deeply, and the memories of our visit will be handed down as traditions to future members of our Institute, who, in the days to come, will, we trust, again seek the aid of Sweden by supplementing the ores of our own possessions with those from within the Arctic circle.

From the technical point of view, as the eighteenth century closed, a new era in the metallurgy of iron had already begun. Abraham Darby had successfully introduced the use of coke in the blast-furnace; James Watt had, by his powerful engines, much facilitated the production of blast, and had greatly stimulated the out-turn of pig iron. Nevertheless, the total annual production of pig iron in the year 1799 did not exceed some 150,000 tons. From the scientific point of view the situation was one of singular interest. The early writers held that good and bad qualities might be inherent in the iron itself. Pliny points out how greatly the properties of iron depend upon its treatment, but he thought that as for the kinds of iron, they were many and all were distinct, and the first difference arises from the diversity of the soil and climate where the mines are found. But Pliny's view survived far into the present century, and evidence of it lingered in the effective and graceful speech in which the Member for Merthyr proposed a vote of thanks to our first President on the delivery of his inaugural address. Mr. Fothergill said then that "thirty years ago the idea prevailed universally . . . that good iron was to be found in certain localities, and could be procured from no other place; it was found good in one place and bad in another." He adds: "Enlightened progress of the last thirty years has shown that the quality of iron depends upon the alloy with which it is mixed."

Enduring as the old view as to the influence of locality was, an experimental basis for a more accurate one had been established very shortly before the present century began, and some, at least, knew that the properties of iron depended on the presence or absence of certain other elements. This position was clearly established by the great Swedish chemist, Bergman of Upsala, who had shown that carbon is the element to which steel and cast iron owe their distinctive properties. He had initiated the employment of calorimetric methods in determining the properties of iron and steel. He insisted that the real difficulty is to explain how it is that the presence of 0·5 per cent. of carbon in iron enables the metal to be hardened by quenching from a red heat, or, in his own expressive words, *Ceterum quomodo dimidia centesima, plumbaginem efficiens, tantam provocare possit differentiam, nodus est gordius haud facile solvendus.* Bergman, moreover, anticipated the later phases of modern research by claiming that iron is a polymorphic element, and plays the part of many metals. In this early view as to the allotropy of iron it should be remembered that in 1790 our countryman, James Keir, followed him closely by urging, before the Royal Society, that what we now call passive iron "is really a distinct form of iron, the alteration being produced without the least diminution of its metallic splendour or change of colour."

Clouet's celebrated experiment on the carburisation of iron by the diamond followed. Doubts, however, were not finally set at rest until 1815, when Pepys, a working cutler in London, excluded the possibility of the intervention of furnace gas. But, as soon as the present century had well turned, the industrial world was in possession of the fundamental fact that carbon is the element of dominant importance in relation to the metallurgy of iron. Well might Bergman express astonishment at the action of carbon on iron. Startling as the statement may seem, the destinies of England throughout the century, and especially during the latter half of it, have been mainly influenced by the use of steel. Her steel rails seldom contain more than Bergman's half per cent. of carbon. Her ship-plates, on which her strength as a maritime power depends, contain less than half that amount. It is essential that the significance of this fact should be clearly understood. Our national existence has long depended on iron and steel. They have been the source of our wealth, one of the main elements of our strength, one cause of our maritime supremacy. Hardly a step of our progress or an incident of our civilisation has not, in one way or another, been influenced by the properties of iron or steel. It is remarkable that these properties have been determined by the relations subsisting between a mass of iron, itself protean in its nature, and the few tenths per cent. of carbon it contains. These properties are, it is true, modified either by the simultaneous presence of elements other than carbon, or by the thermal or mechanical treatment of the mass. The growth of our knowledge of the facts constitutes a large section of our scientific and industrial history. The question arises—Was our national progress delayed by the unreadiness of the technical world in England to take advantage of the facts that science had established?

If we consider the position from the point of view of two remarkable men who were looking for the dawn of the nineteenth century as we are for that of the twentieth, we shall, I think, be satisfied that our progress received no check from failure of industrial workers to assimilate the teaching of science. These men were Black and Cort. Of the scientific men then living, the greatest chemist was Black, Professor at the University of Edinburgh, whom Lavoisier had generously acknowledged as his master. Black fully recognised the importance of Bergman's work, and on his own part insisted on the importance of what would now be called the change in molecular energy as the physical basis on which the properties of iron and steel depend. Black, moreover, in his public lectures gave a singularly accurate description of the process of decarburising iron called "puddling," and devised by "a Mr. Cort," with the results of whose work Black was soon to become familiar. Considering how recent the knowledge of the meaning of oxidation really was at the time, Black's statements with regard to the theory of puddling are truly remarkable. Later on he furnished the Government with an elaborate report on the quality of the material obtained by puddling. He showed, by such mechanical tests as the experience of the time suggested, the superiority of puddled iron, and pointed out that it was more suitable than foreign iron for the appliances "on which," as he says, "the lives of our seamen and the safety of our ships have hitherto mainly depended."

At the end of the century we are justly proud of our colonial possessions, and are satisfied that the varied applications of iron and steel will enable us to knit together all parts of the empire. At the beginning of the century, Lord Sheffield, in his "Observations on the commerce of the American States," writing in the early days of Cort's process, shows that it would help to make British iron as cheap as the foreign, an event which he considered would be more advantageous to England than the possession of her American colonies. Black died in 1799, Cort survived till 1800, so that as the eighteenth century closed, the most eminent scientific man and the foremost practical metallurgist of the generation stood side by side. To Cort we owe the greatest technical advance the modern world had seen; to Black the recognition of the importance of molecular energy in relation to metallurgical problems.

The production of pig iron in this country also received a great stimulus from the discovery by Mushet about the year 1800, that the large deposits of blackband ironstone could be utilised. The century opened with, in round numbers, an annual production of pig iron not exceeding 200,000 tons, of which less than one-third was converted into bars and other descriptions of wrought iron. The capital invested was under five millions, and employment was furnished for nearly 200,000 people.

Returning to the scientific aspect disclosed at the dawn of the century, the year 1803 was an eventful one for science. Nevertheless, the impulse given to research was not in the most favourable direction for the advancement of metallurgic art. The influence of a small proportion of carbon on iron had been recognised, but the quantitative relation between the iron and the carbon was only considered as bearing on the

nature of the product, and not at all from the point of view of chemical union. When, therefore, in 1803, Claude Louis Berthollet published his "Essai de Statique Chimique," it appeared that the action, of what for the moment I may be permitted to classify as the action of *traces* upon *masses*, was in a fair way to be elucidated for the following reason. Berthollet pointed out that "in comparing the action of bodies on each other which depends on their affinities and mutual proportions, the influence of mass has to be considered." Unfortunately in succeeding years the views of Prout, the courteous opponent of Berthollet, prevailed, mainly through the powerful aid of Dalton, who published also in 1803 his first table of atomic weights. Hence the phenomena which could not be attributed to fixed atomic proportions were set aside and usually neglected. Evidently the action of one-tenth per cent. of carbon on iron could not be explained by the aid of combining weights. The century was more than half over before a school of eminent chemists arose, who did not insist that matter is minutely granular, but in all cases of change of state made calculations on the basis of work done, viewing internal energy as a quantity which should reappear when the system returns to its initial state.

The production of cast iron and bar iron was rapidly increasing, and the suitability of cast iron and bar iron for the construction of bridges became evident to engineers, among whom Telford was pre-eminent. A distinguished professor, a worker in pure science, came, in the person of Dr. Thomas Young, to the aid of the technical worker. The need of studying the mechanical properties of iron and steel was evident, and Young showed that the work done in permanently extending or in compressing iron or steel could be represented by a coefficient, to which he gave the name of the "Modulus of Elasticity." This coefficient has probably rendered more service in the development of the study of the strength of iron and steel than any other which has been determined. It is of great importance, because upon it depends the deflection which a structure will take under strain. Young, evidently with a view to bring home evidence as to the great rigidity of steel, gives in his original paper a quaint illustration. He therein shows that if "Hook's law holds" a hanging rod of steel would have to be 1500 miles long in order that the upper portions of it might be stretched to twice their original length. I would incidentally point out that on the basis of Young's calculation, such a column 1500 miles high, if it were 1 foot $2\frac{4}{10}$ inches in diameter, would represent the output for the past year of Bessemer steel in this country alone. Statements of this kind had such a singular fascination for Sir Henry, that I have permitted myself a brief departure from chronological order in offering this one.

[The President then referred to the patent granted in 1817 to the Rev. Robert Sterling for the "regenerative furnace," and to the work of S. B. Rogers, who introduced "iron bottoms" in the puddling furnace. An interesting fact was mentioned which justified the claim made in the address, that Rogers was the pioneer of the great process afterwards known as the "basic" process of dephosphorisation. Faraday's work on alloys in 1820, and his discovery of "a carburet of iron" in 1822 was then described, and the merits of Neilson's discovery of the "hot blast" in 1828 were fully dealt with. After a brief reference to the work of Thomas Andrews, of Belfast, on the "heat of combination," the President proceeded to review the theories of the action of the blast-furnace, and especially referred to the work done in the year 1846.]

It was pointed out in 1846 that in the blast-furnace there was evidently a kind of tidal ebb and flow in the relations of carbon and of oxygen, resulting sometimes in reduction, and at others in oxidation or carburisation; but the changes were all capable of more or less simple expression if viewed either from the atomic or the dynamic standpoint. As the furnaces grew in dimensions, their flaming tops threw a lurid glare over the country, and, "like the dying sunset kindled through a cleft," revealed the magnitude of the problems involved in blast-furnace practice, which were seen to be disproportionate to their apparent simplicity.

In the first half of the century efforts were directed mainly to obtaining a material—cast iron containing some $3\frac{1}{2}$ per cent. of carbon, and fusible at a temperature readily attained in the blast-furnace. In the second half of the century, while efforts to obtain this fusible material were increased, attention was also directed to removing the carbon, and obtaining a product which had a melting point of 400° C. (720° F.) higher than cast iron. This product was either cast directly into ingot moulds or recarburised to the extent necessary to constitute the various gradations of steel. Sheffield hardly knew steel except as a material to be used for the manufacture of cutlery, for which she had been famous since the time of Chaucer.

It is characteristic of our British methods that special circumstances and needs, mainly arising in connection with the development of the steam engine and railways, revealed the broad principles by which the production of iron must be governed. It was natural, therefore, as time went on, that in the work of successive inventors the guidance of scientific principles became progressively evident as ill-directed efforts were gradually replaced by the results of systematic experiments.

The second half of the century began with events of strange importance. The Great Exhibition revealed our industrial strength to all nations. The official reporter of the metallurgical group states that 2,250,000 tons of pig iron were annually produced in this country, and that its estimated value was 5,400,000*l*. The annual production had risen in fifty years from two hundred thousand tons to over two and a quarter millions. Sheffield produced at the opening of the century 35,000 tons of steel, of which 18,000 tons were cast steel. Messrs. Turton exhibited a single ingot of steel weighing 2688 lbs., but Krupp showed an ingot of double the weight, for our country was only preparing for the great change which was so soon to enable it to lead the steel manufacture of the world.

A noteworthy feature of the Exhibition was the collection of iron ores of this country exhibited by Mr. Blackwell, who subsequently, and most generously, provided funds for their analysis. With reference to this collection, the reporter points out that in this country "the ores are not carried far, except where there is great facility for transport." This is noteworthy, as before the century was much older an important supply of ore was brought from Spain, and in the near future we may even seek a supply for British furnaces from distant parts of our own empire.

The year 1851 was, moreover, an important one for metallurgy in this country, as it saw, by the wisdom of H.R.H. the Prince Consort, the establishment of the institution which developed into the Royal School of Mines. If the projected scheme of instruction had been fully carried out, the establishment of a general system of technical instruction, which the pressure of necessity is slowly forcing upon us, would have been anticipated by forty years.

The year 1856 will be ever memorable in the metallurgical annals of our nation as that in which Bessemer gave the description of his process to the world at the Cheltenham meeting of the British Association. As regards the process itself, we have too lately lost our great countryman, and many of us are too familiar with the details of his labours to be able either to fully estimate its value or to realise the wonder of its results. Let us try to think of the Bessemer process as I believe those at the end of the twentieth century will, whose views range over a wider perspective than we can command. The economic aspect of the question will naturally strike the metallurgists of the twentieth century. They will see that in 1855 the make of steel in Great Britain did not exceed 50,000 tons, and the cost of the steel produced sometimes reached 75*l*. a ton. They will see that thirty years after the publication of Bessemer's paper the production of Bessemer steel rose to 1,570,000 tons, and that ship plates were sold at 6*l*. 10*s*. a ton. It will be noted that before the century closed, the maximum production of Bessemer steel in this country in one year reached 2,140,000 tons. The scientific aspect of the process will, however, excite their widespread interest, for before the end of the twentieth century, metallurgy will be taught in our older universities. It will be seen that, notwithstanding the title of Bessemer's Cheltenham paper, he recognised and insisted on the fact that the intense heat was engendered by the combustion of the elements within the fluid bath. It will be noted in what close relation the purely scientific work of Thomas Andrews of Belfast, on the heat of combination, stands to that of Bessemer, and that another instance is presented of the dependence of industrial work on pure investigation. Bessemer's proposal to employ a mixture of steam and air will not be ridiculed as it has been, for speculation will be rife as to whether he did not hope that the liberated hydrogen might remove sulphur and phosphorus, notwithstanding the feebly exothermic result of the ensuing combination, and in spite of the cooling effect of water vapour. In view of the fact that

endothermic combinations take place at a high temperature, the possible action of hydrogen as a decarburiser will be dwelt upon. Prof. Noel Hartley's papers upon the thermo-chemistry of the Bessemer process will be read with much interest, Surprise will, however, be widely felt that physicists generally of the last half of the nineteenth century did not see in the lovely flames of lilac, amethyst, gold, and russet, or in the "stars suspended in a flying sphere of turbulent light" which come from the converter, an appeal to fully investigate their cause and to study the dynamic problems presented by the intense heat engendered. Why was not the destination ascertained of the 1000 cubic feet of argon which accompanies the air passing through the metal during an ordinary Bessemer 10-ton blow? Why were not more strenuous efforts made to ascertain the effect of the temperature of the bath on the nature of the metal?

It will be felt that, as the eighteenth century had closed with a clear statement as to the true nature of oxidation, the nineteenth century had seen its magnificent application in the Bessemer process.

As regards the work of Mushet, future generations will, I believe, desire to add nothing to the words of the President of this Institution who, in 1875, had the pleasure of awarding the Bessemer Medal to him. Mr. Menelaus then said "that the application of spiegeleisen . . . was one of the most elegant as it certainly was one of the most useful inventions ever made in the whole history of metallurgy."

Attention must now be directed to the great process for the production of steel which involved the use of the "open hearth."

Sir William Siemens' life was one long and ultimately brilliantly successful effort to apply the kinetic theory of gases and the dynamical theory of heat to industrial practice. He was eminently a practical worker; but the depth and accuracy of his scientific knowledge gives him a place near that of all the great atomists from the time of Lucretius to that of our own countrymen, Graham, Joule, Clerk Maxwell, and Kelvin. In many of Siemens' papers, theory and practice are closely blended. In viewing the results of his labours, it will be seen in future ages that confidence in the trustworthy character of steel was finally established by experiments on metal produced in the regenerative furnace of Siemens. Looking back, it is astonishing with what difficulties the use of steel for structural purposes was beset. In 1859 Sir John Hawkshaw was not permitted by the regulations of the Board of Trade to employ steel in the construction of the Charing Cross bridge. Time will not permit me to indicate the efforts which were made to induce the Board of Trade to remove the serious hindrances to the use of steel, which had "rendered the construction of the projected bridge over the Firth of Forth practically impossible." These efforts were not successful until 1877, when a committee, consisting of Sir John Hawkshaw, Colonel Yolland, and Mr. W. H. Barlow, were able to recommend that the employment of steel in engineering structures should be authorised by the Board of Trade. The steel employed was to be "cast steel, or steel made by some process of fusion, subsequently rolled or hammered"; one condition of such recommendation being that "the greatest load which can be brought upon the bridge or structure, added to the weight of the superstructure, should not produce a greater strain in any part than $6\frac{1}{2}$ tons per square inch."

As regards the use of steel for shipbuilding purposes, in the year 1875 Sir Nathaniel Barnaby asked, "What are our prospects of obtaining a material which we can use without such delicate manipulation, and so much fear and trembling?" He partly answered his own question four years later, when he quoted experimental evidence as to "the recent successes" of open-hearth steel. In 1890 he completed the case by pointing out that naval architects now "have a perfectly regular material, stronger and more ductile" than iron, and he speaks of "our lasting debt of gratitude for the birth and training of that true prince, William Siemens." It is hardly necessary to point out that the country owes the excellent materials used in naval architecture mainly to the productions of the regenerative furnace.

In connection with the production of mild steel, the addition of ferro-manganese to the decarburised bath proved to be most effective. We can hardly over-estimate our indebtedness to those whose perseverance ensured the adoption of mild steel for maritime and other purposes. "Looked at from the standpoint of to-day, when thousands of tons of such steel are made weekly without serious anxiety or trouble, it is scarcely possible to realise the anxieties and difficulties of the days when the manufacture of open-hearth steel was being perfected." To no one is our debt greater than to our Vice-President, Mr. James Riley, who bore a large share of the anxieties of the early days, and whose words are those I have just quoted.

With regard to the great modifications which have been effected in the Bessemer and open-hearth processes, reference must be made to that ample source of information, our *Journal*. It must also be consulted for the history of the appliances for heating the blast, with which the names of Cowper and of Whitwell will always be specially connected.

In speaking of Bessemer and Siemens I have been obliged to depart somewhat from strict chronological order. I must now resume it.

In the year 1866 Graham's first paper on the occlusion of gases by metals was published in the *Philosophical Transactions*. Its results have been far-reaching, and will always be ranged with the metallurgical triumphs of the century.

In the year 1869 our Institute was founded. In view of certain aspects of the treatment which inventors had previously received from their industrial brethren and from the country, it will be evident that the time for its formation had fully come. Taking instances almost at random, I may remind you that Dud Dudley was, as he says, "with lawsuits and riots wearied and disabled" in the seventeenth century, and that Henry Cort was neglected and oppressed in the eighteenth. The great invention of iron bottoms in the puddling-furnace made by Rogers was received with ridicule, and he died in poverty. Popular tradition of Sheffield indicates that possession was obtained of Huntsman's secret "by the heartless trick of a rival." Neilson, though he warmly acknowledges the support he received from certain ironmasters, was treated with singular meanness by others. Heath fought single-handed for fifteen years "against a common purse, the accumulation of the wealth which he had created." Even Bessemer's early statements were received with incredulity and contempt. With the formation of our Institute all this is changed: men place the results of their work and experience freely at the disposal of their brethren, and each fresh advance meets with appreciative consideration. "Vigorous moderateness," wrote the late Walter Bagehot, "is the rule of a polity which works by discussion. . . . It was government by discussion that broke the bond of ages and set free the originality of mankind."

[It was then pointed out, that the history of the iron and steel industry since the formation of this Institute was epitomised by the labours of those who had occupied the presidential chair. The President, therefore, gave a brief sketch of the work done either by the successive Presidents of the Institute, or during their respective terms of office.]

The address then continues as follows: This concludes the list of those who have hitherto presided over the Institute, and it will have been evident that from time to time other interests than those connected with iron and steel have been represented by your Presidents. We were reminded of this fact when the Institute first met, now twenty-four years ago, at Manchester, where we are promised a delightful meeting again next autumn. The Bishop of that great city then welcomed us by a quotation from Virgil, which connects the age of iron with the age of gold. The passage runs thus:—

"quo ferrea primum
Desinet ac toto surget gens aurea mundo."

A President of this Institute who has had the privilege to serve in the Mint, in a sense connects the iron and the golden age. I find that during the course of a long official career I have been responsible for the standard fineness of over one hundred and twenty-one millions of gold coin. This sum is so vast, and the anxiety connected with it has been at times so great, that I am not careful to conceal the pride revealed by this reference to it, as it is an exponent of the financial greatness of the nation which created the age of steel. But I value as highly the means of conducting research and the hope of being useful, which was also given me by the Government when I was appointed Professor of Metallurgy at the Royal School of Mines. I have in the discharge of my duties persistently striven to show that what is called applied science is nothing but the application of pure science to particular classes of problems.

I regret that space will not permit me to consider the progress of the century as measured by the work of our Bessemer medallists. I hope, however, as regards the labours of the foreign recipients of the honour, to deal with them next spring.

The metallurgy of America is so closely interwoven with our own, that I must permit myself a brief reference to four men who stand out from the industrial ranks of our kinsmen. These are Alexander Lyman Holley, the Hon. Abram S. Hewitt, John Fritz, and Prof. Henry Marion Howe. All of them are Bessemer medallists.

It may help us to estimate the value of the labours of the four men whose names I have given if we remember that at the present time the United States export about a million tons of iron and steel a year, while twenty years ago they were not exporting any. We may also fairly consider their influence on the rapid development of the United States Navy. It would seem that we, in this country, in the belief in our insular security, had somewhat neglected the art of naval warfare, until Admiral Mahan reminded us of what we had done in the past, and of our possible course in the future, in a series of writings which have done much to convince the two nations, England and America, "that they are in many ways one."

It is time to offer a collective statement of the achievements which have either been actually effected or are in immediate prospect.

There are blast-furnaces which will produce 748 tons of pig iron in twenty-four hours, with a consumption of little over 15·4 cwts. of coke per ton of iron. The gases from blast-furnaces are used, not only as sources of heat, but directly in gas-engines.

There are Bessemer converters which can hold 50 tons of metal, and open-hearth furnaces which will also take 50 tons, while 100-ton furnaces are projected. The open-hearth furnaces are fed with one ton of material in a minute, by the aid of a large spoon worked by an electro-motor. There are gigantic "mixers," capable of holding 200 tons of pig iron, in which, moreover, a certain amount of preliminary purification is effected.

Steel plates are rolled of over 300 feet in area and 2 inches thick. There are girders which justify the belief of Sir Benjamin Baker that a bridge connecting England and France could be built over the Channel in half-mile spans. There are ship-plates which buckle up during a collision, but remain water-tight.

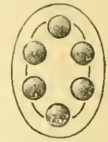
There are steel armour piercing shot which will penetrate a thickness of steel equivalent to over 37 inches of wrought iron. The points of the shot remain intact, although the striking velocities are nearly 2800 feet a second. There are wires which will sustain a load of 170 tons per square inch without fracture. Hadfield, whose labours will, I trust, be continued far into the twentieth century, has given us manganese-steel that will not soften by annealing; while Guillaume has studied the properties of certain nickel steels that will not expand by heat, and others that contract when heated and expand when cool. Nickel, chromium, titanium, and tungsten are freely used alloyed with iron, and the use of vanadium, uranium, molybdenum, and even glucinium, is suggested. There are steel rails which will remain in use seventeen years, and only lose 5 lbs. per yard, though fifty and a half million tons of traffic have passed over them.

Huge ingots are placed in soaking pits and forged direct by 120-ton hammers, or pressed into shape by 14,000-ton presses. With such machinery the name of our late Member of Council, Benjamin Walker, will always be connected.

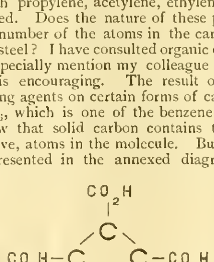
There are steel castings, for parts of ships, that weigh over 35 tons. We electrically rivet and electrically anneal hardened ship-plates that could not otherwise be drilled. Photomicrography, originated by Sorby in 1864, now enables us to study the pathology of steel, and to suggest remedial measures for its treatment. Stead's work in this field is already recognised as classical. Ewing and Rosenhain have, in a beautiful research, recognised quite recently by its aid that the plasticity of a metal is due to "slip" along the cleavage planes of crystals. Osmond also by its aid shows that the entire structure of certain alloys may be changed by heating to so low a temperature as 225° C.

Passing to questions bearing upon molecular activity, we are still confronted with the marvel that a few tenths per cent. of carbon is the main factor in determining the properties of steel. We are, therefore, still repeating the question, "How does the carbon act?" which was raised by Bergman at the end of the eighteenth century. Nevertheless, from the molecular point of view, much may be said in answer to the question. The mystery is in fact lessened now, as it is known that the mode of existence of carbon in iron follows the laws of ordinary saline solutions. Our knowledge is, however, of very recent origin, and we owe mainly to the Alloys Research Committee of the Institution of Mechanical Engineers the development of Matthiessen's view that there is absolute parallelism of the solution of salt in water and carbon in iron.

An ice-floe in a Polar sea contains a small percentage of salt; a red-hot ingot of mild steel holds some two-tenths per cent. of carbon, but both the carbon and the salt are in the state of *solid* solution. If the ice had been cooled below – 18° C., it would entangle a solidified portion of salt water, which was the last part of the mass to remain fluid. So in the steel ingot, when it has cooled to the ordinary temperature, there is a solidified "mother liquor" of carburised iron. We do not as yet know whether carbon is dissolved in fluid iron as carbon or as a carbide. We do know, however, that the presence of 0·5 per cent. of carbon in iron (such an amount as might occur in a steel rail) lowers the melting point of the iron from 1600° C. to 1530° C. This lowering has enabled a calculation to be made, the result of which shows that the number of atoms in a molecule of carbon in *fluid* iron at this temperature is probably *two*. It can be shown that at a temperature of 800° C. the number of atoms in the molecule of carbon dissolved in *solid* iron is, in all probability, *three*. At lower temperatures, the number of atoms is probably more than three. We metallurgists are not accustomed to think in atoms. Let me, therefore, represent such a three-atom molecule thus,  without assuming how much iron is associated with the carbon. Following Bergman's experimental method, but with the interval of more than a century separating his work from ours, we investigate the action of acids on carburised iron with a view to ascertain the nature of the atomic grouping of the carbon.



In explaining this, I may adopt the appended figure. It is most difficult even to attempt to make questions of atomic grouping clear in a paragraph, but the figure will be helpful. To the historian it suggests vivid pages of Italian history, as the six spheres so arranged constitute the arms of the powerful family of Medici. To the chemist it is a precious symbol, and appeals to him as representing the carbon atoms as grouped in the benzene ring. The result of treating carburised iron with various acids is the formation of marsh-gas and more complicated organic compounds, of which propylene, acetylene, ethylene, and naphtha may be mentioned. Does the nature of these products help us to ascertain the number of the atoms in the carbon molecule as it exists in cold steel? I have consulted organic chemists, among whom I would specially mention my colleague Dr. Wynne, and their evidence is encouraging. The result of the action of powerful oxidising agents on certain forms of carbon is mellitic acid, $C_6(CO_2H)_6$, which is one of the benzene series, and this favours the view that solid carbon contains twelve, or some multiple of twelve, atoms in the molecule. But mellitic acid is graphically represented in the annexed diagram, the carbon



atoms being arranged as the six spheres are in the arms of the Medici. The group $CO_2H$ is tacked on to each carbon sphere. From this it may be argued that the molecule of solid carbon consists or one or more carbon "rings." In cold steel, the group of $CO_2H$ may be replaced by the group $Fe_3$, which is broken off by the action of suitable solvents leaving free carbon. Hence the six-atom carbon molecule may exist in steel.

My object is merely to show you how far at the end of the century we have advanced in our knowledge of the mode of action of carbon, and I trust it will be evident that the progress is remarkable. We know that even in solid iron the carbon atom must push and thrust with great vigour, for we can measure the "osmotic pressure" the carbon atom exerts, and, as has just been shown, we can even picture the mode of the atomic grouping in the molecule.

I can only just sum up the evidence as to the occurrence of molecular change in iron. To Gore, and to Barrett, we owe the investigation of the nature of a fact which had long been well known to smiths, that iron on cooling from a bright red heat suddenly emits a glow. We now know that as steel cools down there may be at least six points at which molecular change occurs, accompanied by evolution of heat.

In a series of classical papers of which we are justly proud, for many of them have been communicated to this Institute, our member, Osmond, has shown what is the significance of some of these points, and has won an enduring reputation. We measure and record them photographically as readily as if they were barometric variations. It is known that three points occur in the purest electro-iron yet prepared. Two points are connected with the magnetic permeability of iron. One point at least is due to the power iron has of dissolving carbon. In some cases, two points occur far below a red heat, and appear to be due to the presence of hydrogen. Moreover, the molecular condition of steel cooled from an intense white heat is not the same as that of steel which has just been melted. To carry further the evidence as to the effect of an intense heat on iron in a vacuum is the task I have in prospect during my presidency of the Institute. I may, however, express my agreement with Lockyer's view that the evidence afforded by the atmosphere of the stars shows that our terrestrial iron is a very complex form of matter.

We must not lose sight of those relations of carbon and iron which involve physical equilibrium. Even the astonishing associations of iron and carbonic oxide in the volatile gaseous compound with which the distinguished name of Mond is connected affords a triumph of dynamic chemistry. It is generally supposed that ozone is dissociated at 160° C., but Dewar has devised a beautiful experiment to prove that ozone has two centres of stability, and one of these is near the melting point of platinum. It seems to be the same with the relation of hydrogen and iron. We have recently learned that iron and hydrogen appear to be completely dissociated at 800° C., and yet the same iron heated to some higher temperature, say 1200° C., will still yield hydrogen.

Let us suppose that Black, Cort, and Bergman were with us again, and had reviewed the present state of our knowledge and the work accomplished in the century. Let us also suppose that they could go to Sheffield and see an armour-plate rolled and finished for service, and then, visiting our Institute, hear the best explanation we could offer of all the incidental phenomena they had witnessed. Which would they consider the more advanced, our practice or our theory? They would probably hesitate to tell us, but would offer warm congratulations on the immediate prospect of the establishment of a National Physical Laboratory, in which investigations as to the properties of iron and steel will be continued.

## THE IRON AND STEEL INSTITUTE.

THE annual meeting of the Iron and Steel Institute was held on May 4 and 5 at the Institution of Civil Engineers. The chair was occupied at the beginning of the proceedings by Mr. E. P. Martin, the retiring president. The report of the Council was read by the secretary, Mr. Bennett Brough, and showed that during the year 98 new members had been elected, and that the Institute had maintained its prosperous and satisfactory condition. Sir William Roberts-Austen then took the presidential chair, and delivered an inaugural address, which is printed in an abridged form in another part of this issue. A vote of thanks to the president for his address was proposed by Sir Bernhard Samuelson, seconded by Sir William H. White, and carried by acclamation.

The first paper read was by Mr. H. Bauerman on the Gellivare iron mines, the important mineral region situated in 67° 11′ North latitude and 20° 11′ East longitude. The paper gave a detailed geological description of the mineral deposits, and formed a valuable supplement to previous descriptions of these mines. In the discussion which followed, Mr. W. Whitwell pointed out the importance of this Swedish source of supply in view of the approaching exhaustion of the Spanish deposits, and Mr. H. G. Turner remarked on the similarity of some extensive magnetite deposits in Southern India.

Mr. A. P. Head read a paper on tilting open-hearth furnaces which are coming into use in the United States, and present a substantial advance in metallurgy likely to have far-reaching effects in the future of the relative positions of the Bessemer and open-hearth processes. An interesting discussion followed, in which Mr. Wellman, of Chicago, and Mr. R. M. Daelen, of Düsseldorf, took part.

Prof. Henry Louis then described a dipping needle he had devised for use in exploring for iron ore deposits, which presented decided advantages over the instruments described by Mr. B. H. Brough in 1887, and by Prof. Nordenström last year.

A paper by Prof. J. Wiborgh, of Stockholm, on the use of hot blast in the Bessemer process, was then taken as read. In this the author urged the advantages that would be derived from the use of the hot blast for small converters and for the basic Bessemer process.

The meeting then adjourned until May 5, when a paper by Prof. J. O. Arnold and Mr. A. McWilliam on the diffusion of elements in iron was read. An animated discussion followed, in which Mr. Stead, Mr. Hadfield, Mr. Harbord, Dr. Stansfield and Prof. Louis took part.

A voluminous paper by Baron Jüptner von Jonstorff, on the solution theory of iron, was taken as read. In two previous communications he sought to apply the laws of solution to iron and steel, and in this third paper he carries the research further. He finds that carbon is dissolved as such in pure iron by a sufficiently high temperature. The molecule of the dissolved carbon between 1600° and 1300° C. consists of two atoms. It increases with decreasing temperature, and at 1150° C. nearly equal amounts of two and three atom molecules are present in the solution. At a still lower temperature, there is in the solution, besides a certain amount of free carbon increasing with the content of carbon present, iron carbide. At first the latter remains in solution with the free carbon (austenite). If, however, its quantity increases above a certain amount, the alloy separates into two parts. In the one the free carbon prevails, in the other the carbide of iron (martensite) prevails. With falling temperature, the amount of the iron carbide increases, as also does the martensite, whilst the quantity of the austenite decreases until at length only martensite is present.

Mr. Enrique Disdier contributed a paper on the use of blast-furnace and coke-oven gases, in which he urged that coke-oven gases should be heated by blast-furnace gases and the oven gases used for driving gas engines. By the adoption of this method of utilising the gases, the cost of pig-iron would, he asserts, be reduced by 5*s.* 5½*d.* per ton. In the discussion, Mr. James Riley expressed the opinion that the author had worked out his case well, but considerable difficulties would have to be surmounted before his theory was put into practice. Mr. Hugh Savage described the progress that had been made in Belgium in the use of blast-furnace gases as motive power. Mr. Charles Wood and Mr. Enoch James anticipated difficulty from the dust in the gases.

Mr. Bertrand S. Summers, of Chicago, contributed a lengthy paper on theories and facts relating to cast-iron and steel. In the discussion, Mr. R. A. Hadfield expressed the opinion that there was a demand among electricians for material of high permeability and of low cost, and he thought that the author had done much to render this possible. Mr. W. Mordy also discussed the paper from the electrician's point of view.

The last paper on the list was from the pen of the great Russian metallurgist, Mr. D. Tschernoff. It described a construction of blast-furnace in which gas is used in lieu of solid fuel, and in which iron or steel may be produced direct from the ore.

The usual votes of thanks were carried, and the meeting, which throughout was largely attended and most successful, was declared at an end. On the evening of May 4, the annual dinner was held at the Hotel Cecil, and on May 5 the members were entertained by Sir William and Lady Roberts-Austen at their residence in the Royal Mint.

## THE ROYAL SOCIETY'S CONVERSAZIONE.

THE first of the two soirées held annually at the Royal Society took place on Wednesday, May 3. There was a large collection of apparatus and many interesting exhibits, but our space only permits us to refer to some of those which attracted most general attention; these are as follows:—

Mr. Thomas Andrews, F.R.S., exhibited microscopic structure of heavy steel guns, projectiles, and warship propellor shafts.

The Tsetze Fly Committee of the Royal Society showed enlarged photographs, taken by Surgeon-Major Bruce, illustrating districts in South Africa affected by the Tsetze Fly Disease.

Mr. A. Mallock exhibited thin films used as mirrors. The films are formed by allowing a solution of pyroxyline in amyl acetate to spread on the surface of water. The films being removed when the solvent has evaporated, are then stretched over rings, whose edges have been ground to a true plane, and silvered.

Dr. Patrick Manson and Surgeon-Major Ross exhibited the development of *Filaria nocturna*, Manson, and of *Proteosoma grassii*, Labbé (one of the parasites of malaria of birds), in the mosquito.

Prof. W. N. Hartley, F.R.S., and Prof. J. J. Dobbie exhibited photographs of absorption spectra of organic compounds, showing the method of investigating peculiar cases of isomerism called tautomerism or desmotropy.

Mr. Edwin Edser showed the phase-change associated with the reflection of light from a fuchsine film. Two unsilvered glass plates, forming the end mirrors of a Michelson interferometer, are provided with films of fuchsine on their back surfaces. A horizontal strip of fuchsine is removed from one of the mirrors. Interference fringes are produced by means of rays of light reflected from the fuchsine films; these fringes are focussed on the slit of a spectroscope. The resulting spectrum is found to be crossed by vertical dark bands. In the violet and blue, the bands formed by reflection, in the glass, from fuchsine and air respectively, are seen to be continuous. Since fuchsine is optically less dense than glass for blue light, this is in agreement with theory. Passing onward toward the red end of the spectrum, a gradual displacement occurs in the bands produced by the light reflected from the fuchsine. Red light is seen to be retarded by half a wave-length when reflected from fuchsine.

Mr. Shelford Bidwell, F.R.S., exhibited experiments demonstrating multiple vision; Mr. James Swinburne, Nernst electric lamps; Dr. Woodward, F.R.S., a selection of zoological specimens from Christmas Island (Indian Ocean), collected by Mr. C. W. Andrews; Dr. Francisco P. Moreno, Director of the La Plata Museum, Argentine Republic, portion of skin of an extinct ground-sloth, named *Neomylodon listai* by Ameghino, from a cavern in Southern Patagonia; and Dr. G. Herbert Fowler, examples of floating organisms from the surface and deep water of the Faeroe Channel.

Sir W. Crookes, F.R.S., exhibited new photographic researches on phosphorescent spectra. It has long been known that certain substances enclosed in a vacuous glass bulb phosphoresce brightly when submitted to molecular bombardment from the negative pole of an induction coil. The ruby, emerald, diamond, alumina, yttria, samaria, and a large class of earthy oxides and sulphides emit light under these circumstances. Examined in a spectroscope, the light from some of these bodies gives an almost continuous spectrum, while that from others, such as alumina, yttria and samaria, gives spectra of more or less sharp bands and lines. The exhibitor showed photographs of a group of lines high up in the ultra-violet region, characteristic of a new element associated with yttrium, and separated by long fractionation. To this element the name Victorium has been given. The atomic weight of Victorium is probably near 117. In the purest state in which it has yet been prepared, Victoria is of a pale brown colour.

The Marine Biological Association showed (1) methods of feeding of marine animals, illustrated by living and preserved examples; (2) charts illustrating the distribution of the fauna and bottom-deposits near the thirty-fathom line from the Eddystone Grounds to Start Point.

Mr. Adam Hilger showed the Michelson echelon grating spectroscope.

Prof. Arthur Thomson exhibited a model to illustrate how natural curliness of the hair is produced. Three factors require consideration in the production of curly hair: (1) the hair shaft, (2) the hair muscle, and (3) the sebaceous gland. Straight hair is always circular on section, and is usually thicker than curly hair, which is ribbon-like and fine. In order that the muscle may act as an erector in the hair, it is requisite that the shaft of the hair embedded of the skin should be sufficiently strong to resist any tendency to bend; unless this be so the lever-like action necessary to produce its erection is destroyed. When the hair is fine and ribbon-like, the shaft is not sufficiently stout to resist the strain of the muscle and naturally assumes a curve, the degree of curvature depending on the development of the muscle, the resistance of the hair, and the size of the sebaceous gland. The curve thus produced becomes permanent and affects the follicle in which the hair is developed, the softer cells at the root of the hair accommodate themselves to this curve, and becoming more horny as they advance towards the surface, retain the form of the follicle, the cells on the concave side of the hair being more compressed than those on the convex side. In this way, the hair retains the form of the follicle after it has escaped from it.

Dr. Sorby, F.R.S., showed (1) Actiniæ and other marine animals killed by menthol and preserved in formalin in a fully expanded condition, and the same mounted as transparent lantern slides. The addition of a little menthol to sea water in which the animals are living causes them to expand very fully, and in many cases to die so. When completely dead they can be transferred to 4 per cent. formalin, and kept thus distended or mounted in balsam as lantern slides. (2) Various marine animals preserved as museum specimens in strong glycerine.

Prof. E. A. Schäfer, F.R.S., exhibited (1) specimens showing that after hemisection of the spinal cord Clarke's column undergoes atrophy on the same side below the lesion; (2) specimens showing that the fibres of the pyramidal tract terminate at the base of the posterior horn and in Clarke's column, and not in the anterior horn; (3) specimens showing that the fibres of the descending antero-lateral tract terminate in the anterior horn.

Prof. H. L. Callendar, F.R.S., exhibited recording pyrometers—platinum and thermo-electric.

Mr. W. Duddell showed an oscillograph for tracing alternate-current wave-forms. This oscillograph is arranged for tracing the wave-forms of potential difference and current in investigations with alternating currents. It is essentially a galvanometer which has the extremely short periodic time of one ten-thousandth (0·0001) second, and which is perfectly dead-beat, and has a sensibility, as arranged, of 300 mm. per ampere.

Prof. Hele Shaw and Mr. A. Hay showed how lines of force in a magnetic field could be determined by the stream lines of a thin film of viscous fluid, and also plotted from mathematical investigation.

Prof. W. F. Barrett showed a new thermo-electric combination, giving a nearly constant electromotive force through a wide range of changing temperature.

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—A meeting of the Junior Scientific Club was held on May 6. Mr. E. H. J. Schuster (New College) exhibited some excellent lantern slides of shore life.—This being the 200th meeting, Mr. G. C. Bourne (New College) read a very interesting paper on the early constitution of the Club, after which the Club adjourned. The officers for the ensuing term are—President, E. Gurney (New College). Secretaries, A. G. Gibson (Christ Church), H. E. Stapleton (St. John's). Treasurer, F. W. A. Fleischmann (Magdalen). Editor, F. W. Charlton (Merton).—Owing to medical advice, Prof. E. Ray Lankester, F.R.S., finds that he will be unable to deliver the Boyle Lecture of this year. Prof. J. G. McKendrick, F.R.S., has consented to take his place, and will lecture on "Musical sensations and the inner ear" on June 13.

CAMBRIDGE.—Prof. Sims Woodhead will deliver an inaugural lecture on the relations of pathology to modern medicine, in the Anatomy Theatre on May 23, at 2.30 p.m.

Mr. P. T. Main (sixth wrangler, 1862), who was for many years Lecturer in Chemistry and Superintendent of the Laboratory of St. John's College, died in his rooms on May 5.

The examinations in Agricultural Science for the University's diploma will extend from June 12 to June 19.

On November 7 two groups of colleges will hold examinations for entrance scholarships and exhibitions in Natural Science. One group includes Pembroke, Caius, King's, Jesus, Christ's, St. John's, and Emmanuel; the other Trinity, Clare, and Trinity Hall. The scholarships are of the value of 80*l.* a year and under. At the first group the subjects of examination are: (1) chemistry, (2) physics (including dynamics and hydrostatics), (3) physical geography (as introductory to geology), (4) animal physiology, (5) biology (including zoology and botany). In all branches of Natural Science there will be an examination in practical work. No candidate will be examined in more than *three* of the subjects numbered (1) to (5). Candidates who wish to offer elementary biology as a subject will be examined by means of the more elementary questions contained in the papers on biology. Opportunity will be afforded to candidates in biology to give evidence of their knowledge of natural history, and opportunity will also be given to candidates in physics to show proficiency in mathematics by means of a paper of a somewhat more advanced character than the *test paper* in mathematics. Those who wish to be examined in physical geography or physiology must give notice to that effect not later than October 23.

Information as to the range of the examination in physical geography may be obtained on application to any of the colleges.

At the second, the subjects are physics and chemistry. Papers will also be set in zoology, botany, physiology, geology, or other tripos subjects, provided that notice be given to the tutor not later than October 10. The notice should be accompanied by a list of the text-books which have been read by the candidate. Candidates for an emolument at Clare College may also offer elementary biology.

Further information may be obtained from any of the college tutors.

---

THE International Congress on Commercial Education was opened at Venice on Thursday last in the Senate Hall of the Doges' Palace. Signor Pascolato, the president, delivered the opening address, in which he bade the foreign representatives cordially welcome. Dr. L. Saignat, representing France, gave a review of the work accomplished in the five previous congresses on commercial education, and thanked the Government and the King and Queen of Italy for the reception accorded to them. Other speeches followed. At the afternoon sitting, the Congress discussed the subject of a commercial school, its purpose, its limits, and its organisation. Other cognate subjects were considered at subsequent meetings. The next Congress will be held in Paris in August 1900.

THE Committee of Council on Education in Scotland has resolved that a sum not exceeding 2000*l.* shall be added to the amount payable under the "Education and Local Taxation Account (Scotland) Act, 1892," towards defraying the cost of the inspection of higher class schools in Scotland, and of the holding of examinations for and granting the leaving certificates of the Scotch Education Department. They have also resolved that a sum not exceeding 2000*l.* shall be set aside for the further encouragement of agricultural education in Scotland, to be distributed on conditions which shall hereafter be set forth by the Scotch Education Department. The remainder of the balance available under the section is to be applied in aid of such higher class secondary or technical schools in Scotland as are not in receipt of grants under the Scotch Code.

IN the House of Commons on Monday, Mr. Gerald Balfour introduced a Bill to establish a Department of Agriculture and other Industries and Technical Instruction in Ireland. Describing the principal provisions of the Bill, the right hon. gentleman stated that, as far as concerned the transfer to the new department of existing Governmental functions, the measure closely resembles its predecessor, but that to the powers and duties formerly proposed to be transferred are now added those of the fishery inspectors and most of the functions exercised by the Science and Art Department. With regard to the machinery and funds for carrying out the work of developing agriculture and other industries, considerable changes have been introduced, and the provisions with respect to technical instruction are new. For the purposes of the Bill there will be placed at the disposal of the department, in addition to certain moneys annually voted by Parliament, a total income of between 160,000*l.* and 170,000*l.* a year. It is proposed that the chief sources of this income shall be the Imperial Exchequer, the Irish Church Fund, and the savings effected under the Judicature Act of 1897. 55,000*l.* is to be allocated to technical instruction of an urban character, and 10,000*l.* will go to purposes connected with sea fisheries. The rest of the money is to be used in connection with rural industries. The department is to be assisted by an agricultural board and a board of technical instruction, and only a minority of the members of these boards will be nominated by the Government. It is to be a general rule that no money is to be spent by the department in any local object without some contribution from local sources. The Bill was read a first time.

IN an address to students of the London Society for the Extension of University Teaching, delivered on Saturday afternoon in the Mansion House, Dr. Hill, Master of Downing College and Vice-Chancellor of the University of Cambridge, made the following remarks with reference to science teaching:—The too early teaching of science is not productive of permanent excellence in that department. The classical boys do far better, for they approach the new subject with an intelligence well drilled, with mental sinews well exercised and developed. The true way of approaching science at school is not to prepare boys for science scholarships, but to let scientific interests run like a thin line through school life—to induce a love of nature and beautiful objects. Experience in examining for the science tripos and the medical examinations is discouraging, and, astonishing as is the knowledge of facts displayed by candidates, their mental grip and conception of principle are unsatisfactory. But it is still to be remembered that a wrangler cannot be turned into a biologist, and mathematics dealing with abstractions are not well calculated to make a man a good observer of nature. The qualities needed for a man of science are many—quickness of observation, tenacity of memory, ratiocinative power—and no one course of study can be trusted to produce those results. The individual, however, is the main element, and there is needed in the several cases presented as great variety of mental as of physical nutriment for the body. In any case, however, wide sympathies are needed; the literary man would be the better for some knowledge of science, and the scientific man for a keen interest in literature. The University is charged sometimes with undue extension into technical subjects—to make men farmers, brewers, lawyers, and the like. It is not so, but the University desires to imbue the farmers and others who came to her with a love of knowledge, an elevated taste, a highly trained intelligence.

A GENERAL meeting of Convocation of the University of London was held on Tuesday, Mr. E. H. Busk, chairman of convocation, presiding. The *Times* reports that the Chairman, in replying to Prof. Silvanus Thompson, stated he could not say that, in the ordinary use of the word, negotiations were in progress for the transference of the business of the University to the Imperial Institute. If there were negotiations in progress they were only in a preliminary stage. The position of the matter was this. A communication was received from the Government requesting that a conference might take place between three representatives of the Treasury, three representatives of the University, and three representatives of the Imperial Institute—nine persons in all, who were to inspect the buildings and the grounds belonging to the Imperial Institute at South Kensington, and to consider whether those premises either were suitable or could be made suitable for the headquarters of the University in any way; and, if so, it was thought that the Government might enter into an arrangement with the authorities of the Imperial Institute which would enable them to make a proposal to the University. The nine representatives were duly appointed; they had inspected the building, but they had not yet reported.—Dr. H. F. Morley moved the reception of the report of the standing committee dealing with the regulations at the matriculation examination, aud recommending various resolutions for adoption by Convocation. The report was received. Dr. Morley then moved a resolution requesting the Senate to adopt for the matriculation examination a scheme of subjects which was in complete accordance with the scheme that was unanimously adopted by the meeting of delegates from the Board of Studies in the Faculty of Arts. After some discussion the scheme of subjects was adopted by the house in the following form:—(1) Latin (two papers); (2) English (two papers); (3) mathematics (two papers); (4) any two of the following five languages:—Greek, French, German, Sanskrit, Arabic; and (5) one of the following five sciences:—Elementary mechanics, elementary chemistry, elementary sound, heat, and light, elementary magnetism and electricity, and elementary botany.

## SCIENTIFIC SERIALS.

*Bulletin of the American Mathematical Society*, April.—Prof. F. N. Cole gives an abstract of the *Proceedings* of the February meeting of the Society. For nearly a year plans have been under discussion for providing facilities for the publication of the increasing number of original mathematical papers produced in America. The Committee appointed at the last summer meeting have reported that it is desirable and feasible that the Society should undertake the periodical publication of *Transactions*, and that a commencement should be made in January 1900.—Nineteen papers were presented at the meeting.—Abstracts are given of papers by Prof. Macfarlane (on the imaginary of geometry), by Prof. Osgood (on a means of generating a function of a real variable whose derivative exists for every value of the argument, but is not integrable), by Prof. Lovett (on a certain class of invariants), by Dr. Snyder (lines of curvature on annular surfaces having two spherical directrices), by Dr. Miller (on the primitive groups of degree 17), by Dr. Dickson (concerning the abelian and hypo-abelian groups), by Mr. Hedrick (on three-dimensional determinants), and by Dr. Ling (an examination of groups whose orders lie between 1093 and 2000).—Prof. Webster exhibited a large number of curves traced by the motion of a rotating top.—Prof. J. M. Peirce follows the above notice with an abstract of his paper on determinants of quaternions, read at the above meeting.—The largest linear homogeneous group with an invariant pfaffian, by Dr. L. E. Dickson, was read at the October meeting of the Society.—Asymptotic lines on ruled surfaces having two rectilinear directrices, by Dr. Snyder, was communicated (partially) at the August and December meetings. There are several diagrams. The theorem discussed is every ruled surface contained in a linear complex has an asymptotic line, all of whose tangents belong to the complex (*cf.* Clebsch, "Ueber die Curven der Hauptstangenten bei windschiefen Flächen," *Crelle*, vol. lxviii.; and Bonnet, "Théorie générale des Surfaces," *Journ. de l'École Polytechnique*, vol. xxxii.).—There are reviews of "Theoretical and Practical Graphics," by F. N. Willson, of "The repertorio di matematiche superiori, i. Analisi per E. Pascal," and of "D'Ocagne's Cours de Géométrie descriptive et de Géométrie infinitésimale." The last two notices are by Prof. Lovett, who also contributes a translation of Prof. G. Darboux's obituary sketch of Sophus Lie (*Comptes rendus*, February 27).—Interesting notes and publications close the number.

*Bollettino della Società Sismologica Italiana*, vol. iv., 1898, No. 8.—Obituary notice of P. Landi.—On the different methods of determining the position of the epicentre in distant earthquakes of unknown origin, by G. Agamennone and F. Bonetti. The authors argue that methods which depend on the length of the interval between the two series of undulations and on their direction cannot give trustworthy results. They prefer one based on the time-records of a particular phase of the movement, and they would make use of the slow-period pulsations rather than the earlier tremors, since the latter may traverse the body of the earth with a velocity depending on the density, while the former travel along the surface with a nearly constant velocity.—Two-component seismoscope, by C. Guzzanti.—Notices of the earthquakes recorded in Italy (November 27–December 31, 1897), by G. Agamennone, the most important being the Umbria and Marches earthquake of December 18–22.

## SOCIETIES AND ACADEMIES.

### LONDON.

**Royal Society**, April 20.—"Studies in the Morphology of Spore-producing Members. IV. Leptosporangiate Ferns." By F. O. Bower, Sc.D., F.R.S., Regius Professor of Botany in the University of Glasgow.

An attempt has been made in this memoir to strengthen the characters derived from the sorus by a fresh examination of its details, and certain of its features are used for purposes of general comparison which have hitherto received little attention; they are:—

(1) The relative time of appearance of sporangia of the same sorus.

(2) Certain details of structure of the sporangium, including its stalk.

(3) The orientation of the sporangia relatively to the whole sorus.

(4) The potential productiveness of the sporangium as estimated by its spore-mother cells, and the actual spore-output.

Observations of these features extending over all the more important living genera, coupled with data of habit and the characters of the Gametophyte as collateral evidence, have led the author to divide the homosporous ferns thus:—

| | | |
|---|---|---|
| Simplices | Marattiaceæ | Eusporangiate |
| | Osmundaceæ | Leptosporangiate |
| | Schizæaceæ | |
| | Gleicheniaceæ | |
| | Matonineæ | |
| Gradatæ | Loxsomaceæ | |
| | Hymenophyllaceæ | |
| | Cyatheaceæ | |
| | Dicksonieæ | |
| | Dennstaedtiinæ | |
| Mixtæ ... | The bulk of the Polypodiaceæ | |

The effect of the observations and comparisons in this memoir is rather confirmatory of the current classifications than disturbing. The divisions suggested would supersede those of Eusporangiatæ and Leptosporangiatæ, though these terms would still be retained in a descriptive sense. If the sub-orders Osmundaceæ, Schizæaceæ, and Marattiaceæ be transferred from the end of the Synopsis Filicum to the beginning, and grouped with *Gleichenia* and *Matonia*, we have the "Simplices" before us. They are characterised by the simultaneous origin of the sporangia. The Gradatæ, in which the sporangia are produced in basipetal succession, include the Cyatheaceæ, Dicksonieæ (*Excl. Dennstaedtia*), Hymenophyllaceæ, and Loxsomaceæ, sequences probably of distinct descent, and probably derivative from some prior forms such as the Simplices; and in the arrangement of Sir Wm. Hooker they hold a position following on the Gleicheniaceæ. The family of Dennstaedtiinæ, founded by Prantl to include *Dennstaedtia* and *Microlepia*, also has its place here, but it leads on by intermediate steps to undoubtedly mixed forms in which various ages of sporangia appear without regular sequence, such as *Davallia*, *Cystopteris*, *Lindsaya*, and the Pterideæ. But this sequence is already laid out in this order in the Synopsis, and it illustrates one at least of the lines along which mixed forms are believed to have been derived from the Gradatæ. No attempt has been made to follow the natural grouping of the Mixtæ into detail, or to test the arrangement of them in the Synopsis. Sufficient has, however, been said to show that the systematic divisions of the ferns now proposed fall in readily with the system of Sir William Hooker, notwithstanding that they are based upon details of which he cannot have been aware.

"The Physiological Action of Choline and Neurine." By F. W. Mott, M.D., F.R.S., and W. D. Halliburton, M.D., F.R.S.

The cerebro-spinal fluid removed from cases of brain atrophy after death or during life, particularly from cases of general paralysis of the insane, produces when injected into the circulation of anæsthetised animals a fall of arterial pressure, with little or no effect on respiration. This pathological fluid is richer in proteid matter than the normal fluid, and among the proteids, nucleo-proteid is present. The fall of blood pressure is due to an organic substance, which by chemical methods was identified as choline.

The nucleo-proteid and choline originate from the disintegration of the brain tissue, and their presence indicates that some of the symptoms of general paralysis may be due to auto-intoxication; these substances pass into the blood, for the cerebro-spinal fluid functions as the lymph of the central nervous system. We have identified choline in the blood removed by venesection from these patients during the convulsive seizures which form a prominent symptom in the disease.

Normal cerebro-spinal fluid does not contain nucleo-proteid or choline, and produces no effect on arterial pressure.

Our proof that the material we have worked with is choline rests not only on chemical tests, but also on the evidence afforded by physiological experiments; the action of the cerebro-spinal substance exactly resembles that of choline. Neurine, an alkaloid closely related to choline, is not present in the fluid;

its toxic action is much more powerful, and its effects differ from those of choline.

The fall of blood pressure is in some measure due to its action on the heart, but is also produced by dilatation of the peripheral vessels, especially in the intestinal area. The drug causes a marked contraction of the spleen, followed by an exaggeration of the normal curves, due to the alternate systole and diastole of that organ.

The action on the splanchnic vessels is due to the direct action of the base on the neuro-muscular mechanism of the blood vessels themselves.

The fall of blood pressure is abolished by atropine. This observation has some bearing on general paralysis, for the arterial tension in that disease is usually high, not low, as it would be if choline were the only toxic agent at work.

*Neurine* produces a fall of arterial pressure, followed by a marked rise, and a subsequent fall to the normal level. Sometimes, especially with small doses, the preliminary fall may be absent. Sometimes, especially with large doses, by which presumably the heart is more profoundly affected, the rise is absent.

The slowing and weakening of the heart account for the preliminary fall of blood pressure.

The rise of blood pressure which occurs afterwards is due to the constriction of the peripheral vessels, evidence of which we have obtained by the use of oncometers for intestine, spleen, and kidney.

After the influence of the central nervous system has been removed by section of the spinal cord, or of the splanchnic nerves, neurine still produces its typical effects.

After, however, the action of peripheral ganglia has been cut off by the use of nicotine, neurine produces only a fall of blood pressure. It therefore appears that the constriction of the vessels is due to the action of the drug on the ganglia.

It produces a marked effect on the respiration. This is first greatly increased, but with each successive dose the effect is less, and ultimately the respiration becomes weaker, and ceases altogether. The animal can still be kept alive by artificial respiration.

The exacerbation of respiratory movements will not account for the rise of arterial pressure; the two events are usually not synchronous, and an intense rise of arterial pressure may occur when there is little or no increase of respiratory activity or during artificial respiration.

After atropine, injection of neurine causes only a rise of blood pressure, which is accompanied with constriction of peripheral vessels.

**Chemical Society**, April 20.—Prof. Thorpe, President, in the chair.—The following papers were read:—The synthesis of some $\beta\beta'$-dipyridyl derivatives from citrazinic acid, by W. J. Sell and H. Jackson. Citrazinic acid yields a nitroso-derivative

$$\mathrm{COOH.C}\!\!\begin{array}{l}\diagup\,\mathrm{CH_2}\text{———}\mathrm{CO}\,\diagdown\\ \diagdown\,\mathrm{C(NO).C(OH)}\,\diagup\end{array}\!\!\mathrm{N},$$

from which a number of dipyridyl derivatives have been obtained.—Action of hydrogen peroxide on carbohydrates in the presence of iron, by R. S. Morrell and J. M. Crofts. Both glucose and lævulose are oxidised by hydrogen peroxide in presence of iron salts with formation of glucoson; under similar conditions, arabinose yields arabinoson.—The condensation of oxalic acid and resorcinol, by J. T. Hewitt and A. E. Pitt. The condensation product of oxalic acid with resorcinol in presence of sulphuric acid contains a compound of the composition $C_{20}H_{14}O_7$, which is probably a carboxylic acid.—Ethyl ammonium sulphite, by E. Divers and M. Ogawa. Ethyl ammonium sulphite is formed by the interaction of ammonia and sulphur dioxide dissolved in alcohol; it is immediately converted into alcohol and ammonium pyrosulphite by water.—Ethyl ammonium selenite and non-existence of amidoselenites (selenosamates), by E. Divers and S. Hada.—The allotropic modifications of phosphorus, by D. L. Chapman. Metallic and red phosphorus are identical, and the vapours of red and yellow phosphorus are also identical; red phosphorus melts, forming ordinary phosphorus, under pressure at the melting point of potassium iodide.—On the interaction of mercurous and mercuric nitrites with the nitrites of silver and sodium, by P. C. Rây.—$\beta$-Isopropylglutaric acid, by F. H. Howles and J. F. Thorpe. A new method of preparing $\beta$-isopropylglutaric acid from ethylic $\alpha$-bromisobutylacetate is given.—The synthesis and preparation of terebic and terpenylic acids, by W. T. Lawrence. $\beta$-Isopropylglutaric acid is oxidised by chromic acid mixture with formation of terpenylic acid; the constitution of the latter is therefore

$$\begin{array}{l}\qquad\qquad\quad\mathrm{CMe_2.O}\text{——}\!\!\urcorner\\ \qquad\qquad\quad\;\;|\qquad\quad\;\;|\\ \mathrm{COOH.CH_2.CH.CH_2.CO.}\end{array}$$

—Position-isomerism and optical activity; the comparative rotatory powers of methylic and ethylic ditoluylglycerates, by P. Frankland and H. Aston.—Fencholenic acid, by G. B. Cockburn. Fenchonoxime, when heated with dilute sulphuric acid, yields a mixture of two nitrites, which in turn give isomeric acids on hydrolysis.—The action of certain acidic oxides upon salts of hydroxy-acids, Part iv., by G. G. Henderson, T. W. Orr, and R. J. G. Whitehead.

**Royal Microscopical Society**, April 19.—Mr. E. M. Nelson, President, in the chair.—The President called special attention to two old microscopes; the first, which had been presented to the Society by Mr. J. M. Offord, was signed "Adams," and was a very interesting model which filled up a gap in the historic collection of the Society. Its probable date was about 1785-95. The second microscope, which had been presented by Dr. Dallinger, was one full of interest, and evidently constructed about the end of the last century; it was the earliest example in the Society's collection of a microscope with rack-work limb.—Dr. Hebb exhibited, on behalf of Miss Latham, two slides of blood which had been stained with methylen blue; one was of normal blood which had retained the blue stain, the other was of blood from a diabetic person; but in this the blue had been discharged, probably by the action of the glucose which is present in the blood in this disease.—Owing to illness Prof. Lionel Beale was unable to be present to read his paper.—Dr. Hebb read a letter from Mr. Bryce Scott, who said if any Fellows cared for West India dredgings rich in Foraminifera, he would be pleased to forward them some.—The President then, on behalf of the Society, presented to Mr. T. H. Powell an enlarged framed copy of the portrait of his father, the late Mr. Hugh Powell, which is issued as a frontispiece in the current number of the *Journal*.—The President then made a few remarks upon the theory and construction of eye-pieces for the microscope.—At the next meeting it is hoped Dr. H. C. Sorby will read a paper on the preparation of microscopical specimens of marine worms, and that there will be an exhibition of pond-life.

PARIS.

**Academy of Sciences**, May 1.—M. van Tieghem in the chair.—On continued groups, by M. H. Poincaré.—Iodine in sea water, by M. Armand Gautier. Iodine does not appear to exist in sea water in the form of iodides, since five litres gave a negative result. It would appear to be present in minute organisms, and amounts up to 2·4 mgr. per litre were found from this source. One-fourth of the total amount of iodine present can be separated by filtering through porcelain.—On traumatism and tuberculosis, by MM. Lannelongue and Achard.—Separation into two natural groups of the volcanic outflow of Mt. Dore; the distinctive chemical characters of their magmas, and of that supplying the eruptions of the "puys" of Auvergne, by M. Michel Lévy.—On a generalisation of Fermat's theorem, by M. L. E. Dickson.—On a transcendental equation and linear differential equations of the second order with periodic coefficients, by M. A. Liapounoff.—Note on the development of an arbitrary function and on a series proceeding according to harmonic functions, by M S. Zaremba.—Radioconductors with metallic spheres, by M. Edouard Branly. Columns of from six to fifteen balls of various metals were placed in series with a battery and electric bell. On exposing this column to the electric waves arising from a small induction coil, brusque variations of resistance are set up, causing the bell to ring. Thus with steel the resistance under these conditions fell from 2060 ohms to 120 ohms, with aluminium from 20,660 to 280 ohms, the resistance being in both cases restored by giving a slight shock to the column.—The production of chains of electrolytic deposits, and the probable formation of invisible conducting chains in distilled water under the action of induced currents and electric waves, and on a curious oscillation phenomenon produced in distilled water by induced currents of low frequency, by M. Thomas Tommasina.—On the magnetic rotatory polarisation of quartz, by M. Arnold-Borel.—Chemical analysis of some volcanic rocks arising

from the peripheral cracking of Mt. Dore, by M. E. Bonjean. Eleven analyses are given of phonolites, trachytes, tephrites, and basalts.—On a crystallised double carbonate of cerium peroxide, by M. André Job. The salt has the composition $Ce_2O_3.(CO_3)_3.4K_2CO_3.12H_2O$, and arises from the action of hydrogen peroxide upon cerium salts, and also by spontaneous oxidation.—On a fluorine compound supposed to be contained in certain mineral waters, by M. F. Parmentier. The effects produced upon glass, hitherto supposed to have been produced by fluorides in certain mineral waters, are shown to be due to a deposit of silica. No trace of fluorine has been detected in numerous analyses of mineral waters.—On the oxidising power of the alkaline periodates, by M. E. Péchard. The salt $NaIO_4$ behaves as an oxidising agent towards ferrous salts and potassium iodide.—Displacement of mercury by hydrogen, by M. Albert Colson. Mercuric oxide is slowly reduced by hydrogen at 100°, the amount of mercury formed being proportional to the weight of oxide actually present. The yellow and red oxides are reduced at different rates, the red being the slower of the two. Mercurous oxide is not attacked by hydrogen at 100.—Luminous phenomena produced by the action of certain ammoniacal salts upon fused potassium nitrite, by M. D. Tommasi.—Morphine and its salts, by M. Émile Leroy. A study of the heats of combustion and formation of various salts of morphine.—On the production of the racemoid forms of camphor, by M. A. Debierne.—On the unsymmetrical tetramethyl derivative of diamido-diphenylethane, by M. A. Trillat.—On the sugar from maize stems, by MM. C. Istrati and G. Oettinger.—On the absorption of iodine by the skin and its localisation in certain organs, by M. F. Gollard.—Detection and colorimetric estimation of minute quantities of iodine in organic substances, by M. Paul Bourcet.—The electrical treatment of gout, by M. Th. Guilloz.—On the structure of the anal glands in *Dysticus* and the supposed defensive *rôle* of these glands, by M. Fr. Dierckx.—Sporozoa in the digestive tube of the blind-worm, by M. Louis Léger.—On the quantitative variations of the plankton in the Lake of Geneva, by M. Emile Yung.—Fall of a meteorite recently observed in Finland, by M. Stanislas Meunier.—On a new mercury pump, by M. E. U. Chatelain.

## DIARY OF SOCIETIES.

*THURSDAY*, May 11.

Mathematical Society, at 8.—The Zeroes of a Spherical Harmonic $P_n^m(\mu)$ considered as a Function of $n$: H. M. Macdonald.—On the Statistical Rejection of Extreme Variations, Single or Correlated (Normal Variation and Normal Correlation): W. F. Sheppard.

*FRIDAY*, May 12.

Royal Institution, at 9.—Magnetic Perturbations of the Spectral Lines: Prof. Thomas Preston, F.R.S.

Royal Astronomical Society, at 8.—Observations of Swift's Comet 1899, made at Grahamstown, South Africa: L. A. Eddie.—Observations of Mars made at Mr. Crossley's Observatory, Bermerside, Halifax, during the Opposition 1898–99: Joseph Gledhill.—Note on the Spectra of γ Cassiopeiæ and o Ceti: Rev. W. Sidgreaves.—Longitude from Moon Culminations: D. A. Pio.——*Probable Papers*: Note on an Elbow Form of Reflecting Telescope: Dr. A. A. Common, F.R.S.—Observations of the Satellite of Neptune from Photographs taken with the 26-inch Refractor of the Thompson Equatorial: Royal Observatory, Greenwich.

Physical Society, at 5.—Note on the Vapour Pressure of Solutions of Volatile Substances. Dr. R. A. Lehfeldt.—Note on the Discussion of their Paper on the Criterion for an Oscillatory Discharge of a Condenser: Prof. W. B. Morton and Dr Barton.—Exhibition of a Quadrant Electrometer: G. L. Addenbrooke.

Malacological Society, at 8.—On *Planispira* (*Cristigibba*) *Buruensis* and *Omphalotropis hercules*, New Species from Buru: J. H. Ponsonby and E. R. Sykes.—Note on the Nervous System of *Ampullaria urceus*: R. H. Burne.—Notes on some Marine Shells from North-West Australia, with Description of New Species: E. A. Smith.—Descriptions of *Sigaretus Drewi*, n.sp. (Fossil) and *Cirsonella neozelanica*, n.sp. from New Zealand: R. Murdoch.—Notes on some New Zealand Land Mollusca: R. Murdoch.

*SATURDAY*, May 13.

Geologists' Association (Liverpool Street, G.E.R.), at 2.—Excursion to Ilford.

*MONDAY*, May 15.

Victoria Institute, at 4.30.—The Physical and Mental Attributes of the Sexes: Dr. A. T. Schofield.

*TUESDAY*, May 16.

Royal Institution, at 3.—Recent Advances in Geology: Prof. W. J. Sollas, F.R.S.

Zoological Society, at 8.30.

Royal Statistical Society, at 5.—Life Tables: their Construction and Practical Uses: T. E. Hayward.

Royal Photographic Society, at 8.—Specimens of Work with Irregular Grained Screens, &c.

*WEDNESDAY*, May 17.

Royal Meteorological Society, at 4.30.—The Mean Temperature of the Surface Waters of the Sea round the British Isles, and its Relation to that of the Air: H. N. Dickson.—Some Phenomena connected with the Vertical Circulation of the Atmosphere: Major-General H. Schaw, C.B.

Royal Microscopical Society, at 7.30.—Exhibition of Pond Life.

*THURSDAY*, May 18.

Royal Society, at 4.30.—Bakerian Lecture: The Crystalline Structure of Metals: Prof. Ewing, F.R.S., and W. Rosenhain.——*Probable Papers*: The Yellow Coloring Matters accompanying Chlorophyll and their Spectroscopic Relations: C. A. Schunck, F.R.S.—The Diffusion of Ions into Gases: J. S. Townsend.—The Diurnal Range of Rain at the Seven Observatories in connection with the Meteorological Office, 1871–1890: Dr. R. H. Scott, F.R.S.

Institution of Electrical Engineers, at 8.—Electric Locomotives in Practice and Tractive Resistance in Tunnels, with Notes on Electric Locomotive Design: P. V. McMahon.

Chemical Society, at 8.—Corydaline, Part VI.: Dr. J. J. Dobbie and A. Lauder.—Oxidation of Furfural by Hydrogen Peroxide: C. F. Cross, E. J. Bevan, and T. Freiberg.

*FRIDAY*, May 19.

Royal Institution, at 9.—Runic and Ogam Characters and Inscriptions in the British Isles: The Lord Bishop of Bristol.

## BOOKS, PAMPHLETS, and SERIALS RECEIVED.

Books.—Zur Anthropologie der Badener: O. Ammon (Jena, Fischer).—A Class-Book of (Elementary) Practical Physiology: Dr. de B. Birch (Churchill).—Geometrical Drawing: E. C. Plant, Vol. 1, Practical Plane Geometry (Macmillan).—Medical Missions in their Relation to Oxford: Sir H. W. Acland, 2nd edition (Frowde).—The Hygiene of the Mouth: R. D. Pedley (Segg).—Die Physikalischen Erscheinungen und Kräfte ihre Erkenntnis und Verwertung im Praktischen Leben: Prof. L. Grunmach (Leipzig, Spamer).—Outlines of Physical Chemistry: Prof. A. Reychler, translated by Dr. J. McCrae (Whittaker).—L'Éclairage a Incandescence par le Gaz et les Liquides Gazéifiés: P. Truchot (Paris, Carré).—Transactions of the American Pediatric Society, Vol. x. (New York).—Elements of Quaternions: Sir W. R. Hamilton, 2nd edition, Vol. 1 (Longmans).—Mechanics applied to Engineering: Prof. J. Goodman (Longmans).—Text-Book of Practical Solid Geometry: Captain E. H. de V. Atkinson (Spon).—Steinbruchindustrie und Steinbruchgeologie: Dr. O. Hermann (Berlin, Borntraeger).—The Naval Pioneers of Australia: L. Becke and W. Jeffery (Murray).—Applied Geology: J. V. Elsden, Part 2 ("Quarry" Publishing Company).—A Guide to Recent Large Scale Maps (London).

Pamphlets.—Mines and Quarries, General Report, &c., for 1898, Part 1 (London).—The Geology of the Country around Carlisle: T. V. Holmes (London).

## TRAVELS IN NEW GUINEA.

*Through New Guinea and the Cannibal Countries.* By H. Cayley Webster. Pp. xvii + 387. (London: T. Fisher Unwin, 1898.)

AFTER perusal of this book we are not able to say that its title is strictly descriptive of its contents. It s as regards New Guinea too comprehensive, and too vague in respect of "the Cannibal Countries." It deals with adventurous cruises on the New Guinea coast, and among the islands from the Admiralty Group to the Solomons, with a land journey undertaken in German New Guinea. Of this our author says:

"In the interior of German New Guinea I traversed a greater distance on foot than any white man has done before or since, and on that expedition I discovered the non-existence of a range of mountains previously marked on the chart."

The printing of the book is as excellent as is the paper. The illustrations, some three hundred and fifty in number, are generally good, sometimes excellent. It contains one map, the weakest part of the work. It takes no heed of latitude or longitude, makes Captain Webster more than half cross New Guinea, and sail recklessly over great islands. It is in every respect inferior to older maps. The style of the book is light and easy; the spelling of German names inaccurate. Captain Webster is in some ways typical of the travelling Englishman, ready to go anywhere, but by preference where there is danger to be incurred, and with a mission to put right whatever he finds wrong. We meet him engaged in this way at Batavia, where we take up his narrative. On the German steamer were many coolie labourers. The Government agent kicked, bullied, and ill-used them till Captain Webster, who was only a passenger, interfered. But our author is also an enthusiastic collector. He writes:

"One of my earliest captures [in German New Guinea] was a magnificent specimen of the *Ornithoptera paradisea*, of which only one specimen had before reached Europe, and I felt that it was worth the whole of my journey to New Guinea to see this superb insect lying glistening in my hand."

On November 9, 1893, he reached the headquarters of the New Guinea Company, and received every kindness and assistance from the Governor. A day or two afterwards he saw a coolie flogged for having induced some others to run away. He thought the terrible punishment inflicted exceeded the offence. He found the natives true Papuans, but wisely abstains from describing a Papuan. Captain Webster noticed a strong Hebrew type running through their features, "as indeed I have seen throughout the whole of the country, both in British, German, and Dutch possessions." Surely he did not find this common from Hale Sound to Kiriwina.

He observes that they all smoke tobacco—apparently speaking of the natives of German New Guinea—"which has been introduced into the country by Europeans." He states that he has "on more than one occasion observed a mere infant remove the pipe from his mouth to refresh himself from the natural food provided by his mother." This we presume is to be regarded as a figure of speech.

The introduction and distribution of the tobacco-plant is, however, of real scientific interest. Romilly ("The Western Pacific and New Guinea," p. 226) says of Astrolabe Bay, "Tobacco I should say there certainly was not." He would thus appear to agree with Captain Webster, who carried out his explorations in that district. But Giglioli (p. 120, "I Viaggo del Pattore," O. Beccari) quotes a letter from a Russian officer of the *Vitiaz*, from which Maclay landed in Astrolabe Bay in 1871, which says: "In quanto al tabacco essi [the natives] lo coltivano, e, lo fumano, rivoltandolo in una foglia di banana." On the other hand, we know from the British New Guinea Reports that seven or eight years ago it had not reached the low lands of the large rivers on the north-east coast of that colony.

Our author also relates that he has seen a Papuan woman "nourishing her child and a small pig at the same time, carrying one under each arm, appearing to be more anxious for the welfare of the latter, in consequence of its greater market value." We are aware that if a Papuan woman loses her child she sometimes employs a small pig to remove, and, it may be, to utilise the lacteal secretion. We have, however, never seen a Papuan woman carry her child under her arm, though they do carry dogs and pigs in that way. Captain Webster does not say where he saw this; but at p. 29 we are told what he gave for a small boy. It was more than the market value of a young pig.

Captain Webster's only journey towards the interior was on the watershed of Astrolabe Bay. Romilly wrote:

"Astrolabe Bay has always been looked upon, for some reason unknown to me, as a suitable place for a party of adventurers to swoop down upon and take possession of."

The reason why travellers prefer it is that it offers apparent easy access to the interior. When our author wrote his book, he was evidently unacquainted with the German literature that deals with the Astrolabe Bay district.

The officers of the Russian corvette *Vitiaz* mapped it in 1871, and Guido Cora published the map in 1875. Maclay was in 1871 or 1872 as far inland as the top of the coast range (*Nachrichten über Kaiser Wilhelms Land*, 1896), Zöller and Lauterbach will be mentioned later. The Governor furnished Captain Webster with military police and carriers, under the command of Pierson, who perished later with Herr Otto Ehlers in an unfortunate attempt to cross New Guinea from north to south. It has been claimed for Captain Webster by his publisher that he discovered the Minjim River; he asserts himself that he followed its stream to its source, and he has a photograph of it which purports to say "Hier ist des Stromes Mutterhaus," though it does not look like it. Zöller ("Ersteigung des Finisterre-Gebirges," 1891) found that the road from two German plantations crossed the Minjim. It was, therefore, when Captain Webster arrived in the bay, well known to every one there except himself. Zöller forded the Minjim near the sea, and found it knee-deep in the dry season. In German writings it is sometimes termed a *Bach*, sometimes a *Fluss*. It was in flood when Captain Webster's

party started, but they forded it eleven times in that condition the first day, having, however, many narrow escapes. They left Stephansort on March 22, and reached their furthest distance on April 10. In giving no map of this journey Captain Webster is just neither to himself nor to his reader. Where he really got to, it is quite impossible to say. But this much is clear: that as the Minjim valley runs from the coast towards the Ramu nearly at right angles, and as our author did not reach the Ramu, and never left the watershed of the Minjim, his claim to have beaten the German record falls to the ground, and need not be further considered.

The second and most important geographical discovery of Captain Webster is of a decidedly negative character. He unhesitatingly asserts the non-existence of the great Bismarck Range, of which the German travellers are not a little proud, as it is the highest part of their colony, and on their map a note, "Zeitweise Schnee," appears at a spot where Captain Webster's map makes him cross the range.

The Bismarck Range was discovered and named by Dr. Otto Finsch ("Samoafahrten," 117). He estimated its altitude with wonderful accuracy at 14,000 to 16,000 feet; its distance from the coast at seventy or eighty miles. It was seen by Romilly (*loc. cit.*, 227). Zöller says that in clear weather it is visible from Astrolabe Bay. In his "Routenskizze der Expedition in das Finisterre-Gebirge," Zöller gives the bearings from his highest point on that range to the different summits of the Bismarck Range. These, with bearings from Astrolabe Bay, must give the position with sufficient approximation to accuracy. In 1896, Drs. Lauterbach and Kersting examined the middle course of the Ramu, and actually ascended from thence some of the slopes of the Bismarck Range (*Nachrichten*, 1896, 42) to an altitude of 1000 metres. Lauterbach's positions were determined by astronomical observations, since published. Against this we have the statement of Captain Webster, that from his furthest point he "ascertained the true position of the Albert Victor Range of mountains in British New Guinea," which he thinks was mistaken by "some," who proudly named it after the late ex-Chancellor. In what manner our author ascertained in a few hours the true position of a mountain in British New Guinea from a single unknown and undetermined point on the Minjim will probably remain unknown for all time.

We entertain no doubt that Captain Webster, from his position on the watershed of Astrolabe Bay, was looking at the Bismarck Range itself in the distance. It should interest him greatly to peruse the reports on the splendidly conducted and completely successful expeditions of Zöller (1888) and Lauterbach (1896), and to study their maps, prepared and worked out on scientific principles. If our author will do that, he will wish to rewrite his preface.

In May 1894, Captain Webster visited New Britain just after a massacre of white men, and received the proverbial hospitality of Ralum. He gives an interesting account of how Mrs. Parkinson defeated a native attack, and relates how "the natives for many miles round worship the very ground she walks upon." This follows the very remarkable statement:—

"Within a mile or two of Ralum one may find, even to-day, chiefs who keep slaves for the purpose of food, and who are in the habit of killing them every few days to satisfy their diabolical tastes."

Now there lives at Ralum the enlightened and philosophic Parkinson, a name known to, and deservedly held in high esteem by many of the best men in Europe and elsewhere. That the atrocities mentioned by Captain Webster should be in constant practice under the eye, so to speak, of Mr. and Mrs. Parkinson, it is not easy to comprehend. The attitude of the German authorities is not alluded to by our author. He visited the Sacred Heart Mission, which he pronounced to be "excellent." His historical account of the mission is not quite accurate. The missionaries did not, according to this story, leave Woodlark Island on account of its small size, or of fever, but because they could do nothing with the natives. He states that the country has been divided into Protestant and Catholic countries. We know, from a recent issue of the *Illustrirte Zeitung*, that these divisions are not observed by the Roman Catholic missions in other German colonies. Captain Webster does not say whether the boundaries are respected in New Britain, but he states that the mission is obliged by law to teach the children to read and write German.

He then visited the Solomon Islands, where, as usual, several murders had been committed. He points out that ships of war cannot deal with these matters, a fact that has long been well known to those who study the subject. Captain Webster says the Solomon Islanders are all cannibals, and that the practice of offering up human sacrifices on even the most trivial occasions prevails throughout the group. No information whatever is vouchsafed as to the nature of this strange sacrificial practice.

On page 136, Captain Webster says:—

"I have been an eye-witness to more than one such expedition (head-hunting raids) when a large haul had been made, and more than sixty trophies in the shape of heads had been captured, which were immediately smoke-dried and preserved by being plastered over with chinam."

It is much to be hoped that in the interests of social and political evolution Captain Webster may in the proper place lift the veil on his unique and gruesome experiences. He does not state where or when he assisted at these scenes, which must be very rare. We are not able to believe that "heads" can be preserved in the manner described by our author. The few we have seen had been carefully preserved by a different process, on rational and scientific principles.

Captain Webster brought his visit to the Solomons to a characteristic close by backing out in the presence of a hostile tribe with his face to the foe and his revolver in his hand.

The second part of his book shifts the scene to the Batavian archipelago. On the south-coast of Dutch New Guinea the author met Arab traders, and Christian missionaries who are making very little progress. At the Kei Islands he met his yacht, and was henceforth master of his own movements. He sailed for the nearest part of the New Guinea coast, provided with hunters, and the yacht armed with a quick-firing Krupp gun.

The party next reached British New Guinea. Our author found Port Moresby dreary and dried up. It has often been described as picturesque. He tells us the dress of the men consists "only of a small piece of cord round the waist." The dress does consist of a piece of small cord; but a respectable member of the community would be as much scandalised to appear in public dressed as described by Captain Webster as would be that gentleman himself. The philosophy of clothes offers in New Guinea a great field for the student, but it is not so near the surface as Captain Webster thinks. On the way to Samarai they saw

"numerous villages along the coast, and cocoa-nut trees in great profusion were observed high up on the mountains, but I was informed (says Captain Webster) that the natives were very treacherous and have a bad reputation."

As a matter of fact they are, according to the British New Guinea Reports, under the control of the village police all along the coast from Port Moresby to Samarai, and are settled communities. At Samarai he found "a judge from Queensland presiding there to try the numerous small native cases." It did not occur to Captain Webster that the Queensland judge would have no jurisdiction in another colony. He visited native villages in that district. He describes the weapons of the natives as "bows, arrows and spears." The bow and arrow is, however, not used east of Port Moresby He visited Kwato, and pays a meed of praise to the mission there. He adds:

"At night could be heard far away in the forest weird sounds from their tom-toms and drums, wailings and shouting, which told us that their lewd dances and other disgusting orgies were taking place."

This is a *tour de force* of the imagination fit for the "Inferno" of the Divina Commedia. In sober fact there is no man within "tom-tom" range of Kwato that is not a church-goer. The great fault one really has to find with their dances is their dull, dreary monotony. The disgusting orgies are not scientific facts. John Knox said to his Queen:

"And of dancing, madam, I do not utterly damn it."

He was right. No wise Government will try to put down dancing, especially in a coloured population. Its suppression has been attempted more than once in the Pacific. In the code of M. Tardy Montravel it was enacted:

"13° Toute danse nocturne est interdite. Les delinquants seront punis d'un emprisonnement de un à trois jours."

Of this Paul Cordeil, chief of the Judicial Service of New Caledonia, writes:

"Les codes de M. de Montravel sont toujours restés lettre morte."

Let legislators and travellers take warning accordingly. Dancing is, next to eating, the greatest enjoyment the Papuan has. The drum is silent only after death or disaster. It is only unacquaintance with the drum and the dance that connects these with heinous sin. Assignations are doubtless made at dances. They would be made in any case. It was in church that Petrarch fell in love with Laura, and Boccaccio with Fiametta.

Nothing noteworthy occurred after the party left Kwato till they met with the "duk-duk" in the German Islands. Captain Webster thinks it was invented in the Duke of York group as a form of native police. His view of it is far too narrow. Many natives came off to them on the coast of New Ireland. "They are all ferocious cannibals and very treacherous. Many had been to Fiji, to Samoa, and Queensland, but they are none the more to be trusted." They landed at New Hanover, assisted at some festivities, saw some pretty dances, and obtained photographs. Of course these dances were seen by Captain Webster, and were decent. Here he "found that the natives have a belief that every man, woman, and child belong to one or other species of birds, according to the lines of the hands." He connects this with the old palmistry of our forefathers. We recognise it as belonging to the totemism that exists or existed from the St. Lawrence to the west end of New Guinea, and probably much further. But we shall before long hear more on this subject from Captain Webster's distinguished host at Ralum.

The party then proceeded to the Admiralty Group, but did not dare to land there.

The last chapter is a summary of anthropology and ethnology. It requires to be regarded cautiously before it can be used for scientific purposes.

The collections made were large. In birds it was disappointing, at least as regards those of the Paradise family. The insects turned out better. The specimens collected are already to be met with in museums from the south of Italy to the north of Germany. Captain Webster has therefore the satisfaction of knowing that, as a collector, he has made a contribution to the sum of human knowledge.

## OUR BOOK SHELF.

*The Philosophy of Memory, and other Essays.* By D. T. Smith, M.D. Pp. 203. (Louisville, Ky.: J. P. Morton and Co., 1899.)

DR. D. T. SMITH is an amateur of philosophy in that wider sense of the word which includes physics, and his speculations, as they are modestly put forward in the present volume, range from psychology to sphere-formation, and from the distinction of organic and inorganic to an adverse criticism of the nebular hypothesis. The essay which gives its title to the book is an attempt, notwithstanding the sterility of the inorganic and the reproductive capacity of the organic, to trace continuity, and apply analogies, from the one to the other, in the form of a physical-vibration theory of ideation. Even conscience is an "orderly operation of ether vibrations with respect to conduct." The second essay, on emphasis or rhythm, is a further application of the wave-theory. The third paper, on "the functions of the fluid wedge," is interesting as suggested by the author's expert physiological studies, and carried out in the alien field of hydrostatics. The present writer confesses to non-comprehension. The fourth essay objects to the nebular hypothesis that the facts of rotation are against it. "The earth could revolve on its own separate axis in the same direction as the sun only by

being caused to move in a larger orbit than that described by it while still a part of the sun's mass," and the author suggests the action of comets carrying off portions of the nebulous border of a sun, as they struck it in the direction of its motion at a suitable moment.

The fifth and last article, in the results of which Dr. Smith expresses confidence other than he shows in respect of his earlier excursions into heterodox and quasi-heterodox physics, is devoted to "the laws of river-flow." Residence on the banks of the Mississippi enabled him to discover the formula of a double spiral action, by which to explain the elevation of the middle of a stream, the drift of floating material from the sides and of sunken material to the sides, the shape and depth of the eroded channels, the different speed of diverse portions of the current. This piece of at any rate unborrowed speculation appears not unworthy of consideration. H. W. B.

*Das Heidelberger Schloss und Seine Gärten in alter und neuer Zeit und der Schlossgarten zu Schwetzingen.* By H. R. Jung and W. Schröder. Pp. 74. (Berlin: G. Schmidt, 1898.)

In this work we have an historical account of the gardens and castles of Heidelberg—the famous German university town, and its less well-known neighbour Schwetzingen. The authors are both gardeners, and, although the book is written chiefly from a garden point of view, a good deal of space is given to purely historical matter. Judging from the photographs, the gardens at Schwetzingen seem to be far more beautiful and natural than those of Heidelberg, where grottoes, shrines, and various other architectural devices appear to be the leading features, and not always ornamental ones either. To those interested in the history of very old and famous gardens, this treatise may be of use; and it will not take up much space on the library shelf, being only about a quarter of an inch in thickness. It is well printed and illustrated, and is practically free from misprints; the only one of any importance being at p. 47, where Azalea appears as Aralea. Were it not that there is a genus Aral*i*a, this slip would not be worth mention.

John Weathers.

*Graduated Test papers in Elementary Mathematics.* By Walter J. Wood, B.A. Pp. 71. (London: Macmillan and Co., Ltd., 1899.)

There are forty test-papers in this collection, each containing questions in arithmetic, Euclid, and algebra. At the head of each test are notes stating the parts of the subjects required in order to solve the questions. The papers are primarily intended to test the progress of students preparing themselves for the examination in first stage mathematics of the Department of Science and Art, and Departmental teachers will find them of real value for that purpose. In the lower mathematical forms of secondary schools, also, the papers should be of service, as many of the questions have been selected from the papers of public examining bodies mostly favoured by such schools. Care appears to have been taken in selecting and arranging the questions, and answers are given to all the questions in arithmetic and algebra.

*The Story of the British Race.* By John Munro. Pp. 242. (London: George Newnes, Ltd., 1899.)

Some time ago Mr. Munro wrote "The Story of Electricity" for this library of useful stories. In this volume he transfers his attentions to the science of anthropology, and expresses in his preface the hope that his book will "tend to destroy some errors regarding the origin and pedigree of the nation which have infected life and literature for ages." The volume should be the means of creating an interest in the study of mankind, in addition to imparting a knowledge of the nature of the races in the British Islands.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature *No notice is taken of anonymous communications.*]

### Fourier's Series.

I have M. Poincaré's authority to publish the accompanying note regarding the applicability of Fourier's series to discontinuous functions, and send it accordingly for publication in Nature. A. A. Michelson.

Mon cher Collègue,—Comme je l'avais prévenu vous avez, tout à fait raison. Prenons d'abord l'integrale $\int_0^y \frac{\sin xz}{x} dx$, dont la limite pour $y = \infty$ est $\pi/4$, 0, $-\pi/4$ selon que $z$ est positif, nul ou négatif.

Faisons maintenant tendre simultanément $z$ vers $o$ et $y$ vers l'infini de telle façon que $zy$ tende vers $a$. La limite sera $\int_0^a \frac{\sin x}{x} dx$ qui peut prendre toutes les valeurs possibles depuis o jusqu'à $\int_0^\pi \frac{\sin x}{x} dx$.

Si nous prenons maintenant $n$ termes dans la série $\Sigma \frac{\sin kz}{z}$ en faisant tendre simultanément $z$ vers $o$ et $n$ vers l'infini de telle façon que le produit $nz$ tende vers $a$, cela sera évidemment la même chose; et la différence entre la somme et l'integrale sera d'autant plus petite que $z$ sera plus petit. Cela se voit aisément. Tout à vous,

(Signed) Poincaré.

### A Note upon Phosphorescent Earthworms.

It has been long known that earthworms may be phosphorescent. So long ago as 1836 Prof. Dugès described, under the name of *Lumbricus phosphoreus*, a worm which showed this peculiarity. In 1887 Prof. Giard showed that a worm probably identical with this, and, if so, not a *Lumbricus* at all, was marked luminous, especially when the soil was disturbed in the vicinity. Giard named the species *Photodrilus phosphoreus.* It has been met with and noticed to be luminous by two other observers. Quite recently (*Zoolog. Jahrbücher*, xii., 1899, p. 216) Dr. Michaelsen, of Hamburg, ascertained that this species of Giard is really identical with *Microscolex modestus* of Rosa. The multiplication of names is hardly the fault of Prof. Giard, since the genus *Microscolex* had only been instituted a few months before his genus *Photodrilus.* This species, unlike the majority of its congeners, which are chiefly congregated in Patagonia, and there very abundant, is not only European, but also occurs in England. It seems also to be, at least usually, phosphorescent. I received some time since, through the kindness of Mr. Carleton Rea, a few small earthworms from the neighbourhood of Worcester, which were undoubtedly a *Microscolex*, and at least not much different from *M. modestus.* Mr. Rea informed me that they were phosphorescent, with a "light emitted exactly similar to that of the glow-worm." They could be stimulated to show this light by "stamping the lawn." It has been suggested that this phosphorescence in earthworms is really due to photogenic bacteria entangled in the slime upon the skin. Possibly such an explanation may account for the occasional phosphorescence of *Allolobophora foetida* (the "Brandling"), observed by Vejdovsky. But the regularity, and the mode of excitation, of the luminosity seems to show that *Microscolex* is phosphorescent in its own right.

Frank E. Beddard.

## ON THE CHEMICAL CLASSIFICATION OF THE STARS.[1]

In the attempts made to classify the stars by means of their spectra, from Rutherford's time to quite recently, the various criteria selected were necessarily for the most part of unknown origin; with the exception of hydrogen, calcium, iron, and carbon, in the main chemical origins could not be assigned with certainty to

[1] By Sir Norman Lockyer, K.C.B., F.R.S. A paper read at the Royal Society, May 4.

the spectral lines. Hence the various groups defined by the behaviour of unknown lines were referred to by numbers, and as the views of those employed in the work of classifying differed widely as to the sequence of the phenomena observed, the numerical sequences vary very considerably so that any coordination becomes difficult and confusing.

Recent work has thrown such a flood of light on the chemistry of the stars that most definite chemical groupings can now be established, and the object of the present communication is to suggest a general scheme of classification in which they are employed, in relation to the line of cosmical evolution which I have developed in former papers communicated to the Society.

The fact that most of the important lines in the photographic region of the stellar spectra have now been traced to their origins renders this step desirable, although many of the chemical elements still remain to be completely investigated from the stellar point of view.

The scheme is based upon a minute inquiry into the varying intensities, in the different stars, of the lines and flutings of the under-mentioned substances :—

Certain unknown elements (probably gaseous, unless their lines represent "principal series") in the hottest stars, and the new form of hydrogen discovered by Prof. Pickering (which I term proto-hydrogen for the sake of clearness). Hydrogen, helium, asterium, calcium, magnesium, oxygen, nitrogen, carbon, silicium.

Iron, titanium, copper, manganese, nickel, chromium, vanadium, strontium ; the spectra being observed at the highest available spark temperatures. The lines thus observed I term enhanced lines, and I distinguished the kind of vapour which produces them by the affix proto, *e.g.* proto-magnesium, for the sake of clearness.[1]

Iron, calcium, and manganese at arc temperatures.

Carbon (flutings) at arc temperatures.

Manganese and iron (flutings) at a still lower temperature.

In a communication to the Society[2] I stated the results arrived at recently with regard to the appearances of the lines of the above substances in stars of different temperatures, and the definition of the different groups or genera to be subsequently given are based upon the map which accompanied the paper, together with more minute inquiries on certain additional points, the examination into which was suggested as the work went on.

So far as the inquiry has at present gone, the various most salient differences to be taken advantage of for grouping purposes are represented in the following stars, the information being derived from the researches of Prof. Pickering[3] and Mr. McClean,[4] as well as from the Kensington series of photographs.

*Hottest Stars.*

Two stars in the constellation Argo (ε Puppis and γ Argûs).[5]

Alnitam (ε Orionis). This is a star in the belt of Orion shown on maps as Alnilam. Dr. Budge has been good enough to make inquiries for me which show the change of letter to have been brought about by a transcriber's error, and that the meaning of the Arabic word is "a belt of spheres or pearls."

*Stars of intermediate Temperature (Ascending Series).*

β Crucis, ε Tauri, Rigel, α Cygni, [ ] Polaris, Aldebaran.

[1] *Roy. Soc. Proc.*, vol. lxiv. p. 398.
[2] *Roy. Soc. Proc.*, vol. lxiv. p. 396.
[3] *Astro.-Phys. Journ.*, vol. v. p. 92, 1897.
[4] "Spectra of Southern Stars."
[5] The spectrum of this star contains bright lines, but I show in a paper nearly ready for communication to the Society, that when these occur with dark lines, the latter alone have to be considered for purposes of chemical classification.

*Stars of intermediate Temperature (Descending Series).*

Achernar, Algol, Markab, [ ] Sirius, Procyon, Arcturus.

*Stars of lowest Temperature.*

| *Ascending Series.* | *Descending Series.* |
|---|---|
| Antares, one of the brightest stars in Duner's observations of Class III*a*.[1] | 19 Piscium, one of the brightest stars in Duner's Class III*b*. |
| [Nebulæ.] | [Dark Stars.] |

In order to make quite clear that both an ascending and a descending series must be taken into account, I give herewith two photographs showing the phenomena observed on both sides of the temperature curve in reversing layers of stars of nearly equal mean temperatures, as determined by the enhanced lines. The stars in question are :—

Sirius (descending).
α Cygni (ascending).

Procyon (descending).
γ Cygni (ascending).

The main differences to which I wish to draw attention are the very different intensities of the hydrogen lines in Sirius and α Cygni, and the difference in the width and intensities of the proto-metallic and metallic lines in Procyon and γ Cygni.

These differences, so significant from a classification point of view, were first indicated in a communication to the Society in 1887,[2] and the progress of the work on these lines has shown how important they are.

I have based the group—or generic—words upon the following considerations.

As we now know beyond all question that a series of geological strata from the most ancient to the most recent brings us in presence of different organic forms, of which the most recent are the most complex, it is natural to suppose that the many sharp changes of spectra observed in a series of stars from the highest temperature to the lowest brings us in presence of a series of chemical forms which become more complex as the temperature is reduced. Hence we can in the stars study the actual facts relating to the workings of inorganic evolution on parallel lines to those which have already been made available in the case of organic evolution.

If then we regard the typical stars as the equivalents of the typical strata, such as the Cambrian, Silurian, &c., it is convenient that the form of the words used to define them should be common to both ; hence I suggest an adjectival form ending in *ian*.

If the typical star is the brightest in a constellation, I use its Arabic name as root ; if the typical star is not the brightest, I use the name of the constellation.

The desideratum referred has to a certain extent determined the choice of stars where many were available. I have to express my great obligations to Dr. Murray for help generously afforded in the consideration of some of the questions thus raised. The table runs as follows :—

*Highest Temperature, Simplest Chemistry.*

Argonian.
Alnitamian.

| *Ascending Series.* | *Descending Series.* |
|---|---|
| Crucian. | Achernian |
| Taurian. | Algolian |
| Rigelian. | Markabian |
| Cygnian. | —— |
| —— | Sirian. |
| Polarian. | Procyonian. |
| Aldebarian. | Arcturian. |
| Antarian. | Piscian. |

The chemical definitions of the various groups or genera are as follows :—

[1] "Sur les étoiles à spectres de la troisième classe."
[2] *Roy. Soc. Proc.*, vol. lxi. p. 182.

*Argonian.*

*Predominant.*—Hydrogen and proto-hydrogen.

*Fainter.*—Helium, unknown gas (λ 4451, 4457), proto-magnesium, proto-calcium, asterium.

*Alnitamian.*

*Predominant.*—Hydrogen, helium, unknown gases (λ 4089·2, 4116·0, 4649·2).

*Fainter.*—Asterium, proto-hydrogen, proto-magnesium, proto-calcium, oxygen, nitrogen, carbon.

*Crucian.*

*Predominant.* — Hydrogen, helium, asterium, oxygen, nitrogen, carbon.

*Fainter.*—Proto-magnesium, proto-calcium, unknown gas (λ 4089·2), silicium.

*Achernian.*

Same as Crucian.

Proto-metallic lines relatively thick, hydrogen relatively thin.

*Taurian.*

*Predominant.*—Hydrogen, helium, proto-magnesium, asterium.

*Fainter.* — Proto-calcium, silicium, nitrogen, carbon. oxygen, proto-iron, proto-titanium.

*Rigelian.*

*Predominant.*—Hydrogen, proto-calcium, proto-magnesium, helium, silicium.

*Fainter.*—Asterium, proto-iron, nitrogen, carbon, proto-titanium.

*Cygnian.*

*Predominant.*—Hydrogen, proto-calcium, proto-magnesium, proto-iron, silicium, proto-titanium, proto-copper, proto-chromium.

*Fainter.* — Proto-nickel, proto-vanadium, proto-manganese, proto-strontium, iron (arc).

*Polarian.*

*Predominant*—Proto-calcium, proto-titanium, hydrogen, proto-magnesium, proto-iron, and arc lines of calcium, iron, and manganese.

*Fainter.*—The other proto-metals and metals occurring in the Sirian genus.

Proto-metallic lines relatively thin, hydrogen relatively thick.

*Algolian.*

*Predominant* —Hydrogen, proto-magnesium, proto-calcium. helium, silicium.

*Fainter.* — Proto-iron and proto-titanium.

*Arcturian.*

Same as Aldebarian.

*Antarian.*

*Predominant.* — Flutings of manganese.

*Fainter.*—Arc lines of metallic elements.

*Piscian.*

*Predominant.*—Flutings of carbon.

*Fainter.* — Arc lines of metallic elements.

We may take for granted that as time goes on new intermediate genera will require to be established; the proposed classification lends itself conveniently to this, as there are no numerical relations to be disturbed.

A still more general chemical classification is the following, it being understood that in it only the most predominant chemical features are considered, and that there is no sharp line of separation between these larger groups. The peculiar position of calcium and magnesium render this caveat the more necessary.

Highest temperature.

Lowest temperature.

The detailed chemical facts to be gathered from the definitions of the several genera indicate many important differences between the order of appearance of chemical substances in the atmospheres of the stars and that suggested by the hypothetical "periodic law." Special investigations are in progress by which it is hoped some light may be thrown on this and other points of a like nature.

## THE USE OF PHOSPHORUS IN THE MANUFACTURE OF LUCIFER MATCHES.

OUR readers will be aware that about a year ago the attention of the public was specially directed to the danger which attends the use of yellow phosphorus in the manufacture of matches. Numerous cases of necrosis of the jaw were reported, and some of these occurred in factories which were supposed to be conducted on hygienic principles. There were also some cases in these factories which had been intentionally concealed from the proper authorities. The Home Office accordingly requested Profs. Thorpe and Oliver to inquire and report upon the subject, and shortly afterwards these authorities were joined by Dr. Cunningham, senior dental surgeon to the London Hospital, in view of the importance of the practical dental question at issue.

These three gentlemen have now presented their report, and it has been issued (January 1899) as a Blue Book of 236 pages. It is to be hoped that the Government will see their way to act promptly on the recommendations here set forth, and that by a proper system of inspection they will provide for the carrying out of the new regulations; many excellent rules for the management of match factories already exist, but in some cases these have become practically a dead letter, as they have not been enforced sufficiently stringently.

We have nothing but praise for the way in which the three investigators have carried out their work. Prof. Thorpe deals with the question from the chemical standpoint, and enters into such matters as the differences between the allotropic forms of phosphorus, the composition of phosphorus fumes, their solvent action on teeth, and the composition of the various pastes, &c., used in the manufacture of matches. Full and illustrated accounts of the process of manufacture are given, both in this and in other countries, and the precautions taken to minimise the danger to the workpeople. Dr. Oliver, whose work in connection with other dangerous trades is so well known, approaches the question from

the medical standpoint, and the portion of the report for which he is responsible is clear, concise, and intensely practical. Dr. Cunningham's report contains a full account of phosphorus necrosis, and is illustrated by diagrams showing various stages of the disease in the teeth and jaws. This condition is the most frequent and most obvious of the poisonous effects of phosphorus; it is not by any means the only one. He also gives in full the precautions which should be adopted in all factories for combating the injurious effects of the poisonous fumes. There are various appendices which give in detail the facts upon which the main body of the report is founded.

The whole report is a clear evidence of the painstaking way in which the Commission has carried out of its work, and is specially valuable, seeing that the investigators have visited various foreign countries in order to compare what is being done there with what occurs in our own country. An admirable summary of conclusions is furnished by Dr. Arthur Whitelegge, the chief inspector of factories. The main conclusions are as follows:—

In the match industry two forms of phosphorus are used: *yellow phosphorus*, which is highly poisonous, and gives off poisonous fumes which consist mainly of low oxides of phosphorus; and *red phosphorus*, which does not fume, and is hardly poisonous even if swallowed.

Then, as is well known, there are two principal varieties of matches used: the "safety matches," which are tipped with a composition free from phosphorus; the surface on which they strike is covered with a composition of which red phosphorus forms a part. The "strike anywhere" matches are tipped with a paste containing yellow phosphorus in a proportion which varies from 3 to 30 per cent.; but in this country not more than 6 or 7 and often less than 5 per cent. is used. It is in the making of such matches only that danger arises. Attempts are being made to make "strike anywhere" matches which contain no yellow phosphorus, and rewards have been offered for an effective match of this kind, but up to the present these efforts have not been successful; either such matches do not strike anywhere, or else they are violently explosive.

The specially dangerous processes in the manufacture of matches containing yellow phosphorus are *mixing* the paste, *dipping* the wood or wax stems, *drying* the bundles after dipping, and *boxing* the dried matches; it is the last process which involves the most handling of the matches.

The rules that already exist require (1) natural and mechanical ventilation to be efficient in the rooms where these processes are being carried out; (2) effectual means to prevent the fumes entering other parts of the factory; (3) that no person shall be employed who has suffered from necrosis, or had a tooth extracted; (4) that persons suffering from toothache shall be at once medically examined; (5) notification of cases of necrosis is obligatory; and (6) proper conveniences for washing shall be provided.

Both here and abroad many firms have done a good deal more than this: the dental supervision has been efficient, and the introduction of elaborate machinery instead of hand labour in the four dangerous processes has done more than anything else to lessen the danger. In some foreign countries the precautions taken are in advance of our own, but in this country special praise is given to the Diamond Company's factory at Liverpool, where cases of phosphorus necrosis have never occurred. In Germany, Austria, and Switzerland, there is, however, the surreptitious manufacture of matches as a home industry to be contended with; this disastrous practice has, happily, not been attempted in Great Britain.

The main point which the Commission had to decide was undoubtedly whether they should recommend the use of yellow phosphorus to be prohibited. We may give their decision in their own words:—

"So far as the home consumption is concerned, it does not seem that the prohibition of the use of yellow phosphorus would involve any serious hardship, and this course has already been adopted by Denmark, and decided upon by Switzerland, care being taken at the same time to prohibit the use or importation of yellow phosphorus matches. But neither of these countries has or had any export trade to lose. The United Kingdom, Belgium, Sweden, and Japan, manufacture largely for export,[1] and it is feared that immediate prohibition of yellow phosphorus would at once divert that portion of our trade to other countries, unless international agreement upon the subject was arrived at. If grave injury to the health of the workpeople were inevitable, the loss of the trade might well be regarded as the smaller sacrifice of the two, but the result of the inquiry points to a different conclusion. With due selection of workpeople, strict medical and dental supervision, proper structural and administrative conditions, and substitution of machinery for hand labour, it seems that the dangers hitherto attending the use of yellow phosphorus can be overcome."

We need not go into the details of all the precautions set forth; they will involve revision of the present rules, and put briefly they consist of absolute cleanliness, perfect ventilation, medical selection of workpeople (children, debilitated persons, and those with unsound teeth being excluded), compulsory dentistry, substitution of machinery for direct handling, and limitation of the percentage of phosphorus in the paste.

We learn that in Russia a tax is imposed upon the manufacture of yellow phosphorus matches, with the result that safety matches are displacing the "strike anywhere" kind. The Commissioners make no recommendation that a similar tax should be imposed here; they are also silent in regard to recommendations concerning international agreement in view of the total prohibition of the use of yellow phosphorus. No doubt this would have been the most stringent and the most effective course to adopt. But legislation is a slowly moving machine, and international legislation a more cumbrous one still. Recognising this, the report suggests what is a more practical remedy, and certainly a more immediate one. What has been accomplished by the Diamond Factory at Liverpool should be made compulsory elsewhere, and for the sake of the workers it is to be hoped that there will be no delay in carrying the suggested rules into operation.

## *MIMICRY AND WARNING COLOURS.*[2]

IT is just twenty years ago since the late Charles Darwin called the writer's attention to a little paper, by Fritz Müller, published in *Kosmos* for May 1879, and containing a new suggestion concerning the theory of mimicry. It was the writer's misfortune to have foreseen that the principle discovered by Müller was likely to exert a profound influence on certain biological problems of which the solution had up to that time been unattempted, and he accordingly introduced the new idea to the entomologists of this country by inserting a translation of the paper in the *Proceedings* of the Entomological

[1] For foreign and colonial use, especially in hot and humid climates, the yellow phosphorus matches keep better and resist damp.

[2] "Natural Selection the Cause of Mimetic Resemblance and Common Warning Colours." By Edward B. Poulton, M.A., F.R.S. (*Journ. Linn. Soc. Zoology*, vol. xxvi. pp. 558–612.)

Society of London. The misfortune lay in the circumstance that the entomologists of that time were unprepared for new ideas, and the writer had accordingly to incur the opprobrium of an innovator. He has happily survived this treatment, but how far any advancement has been made by entomologists since the year 1879 may be gathered from the discussion of the whole subject which was raised in the Entomological Society in 1897, and of which a summary is given by Prof. E. B. Poulton in the paper now under consideration. So far as the writer of this notice is concerned, the first gleam of encouragement came from Dr. Alfred Russel Wallace, who, with his well-known power of mental penetration, had no sooner had the case submitted to his judgment than he accepted the new doctrine, and incorporated it in his book on "Darwinism." From the discussion of 1897 it appears that the majority of our entomologists are still hostile to the Müllerian theory; but conspicuous among those who have helped to support and develop it is the author of the paper now before us. We may claim also Dr. F. A. Dixey, of Oxford; Mr. Roland Trimen, one of the early pioneers with Bates and Wallace in the subject of mimicry; Colonel Swinhoe; Dr. A. G. Mayer, of America; Mr. Gahan, of the British Museum, and some few others, as co-heretics in this later development of the theory of mimicry.

The original theory propounded by Bates in 1861 is so well known, and has been so frequently discussed in these columns, that it is unnecessary to restate it. The fundamental condition is that the imitated form should be objectionable to insectivorous enemies, while the mimic should not be protected by any distasteful qualities. The Müllerian theory, briefly stated, is that two or more species belonging to distasteful groups will derive benefit from mimetic resemblance because, although immune as compared with non-protected species, they are not altogether exempt from persecution, and the loss in individuals incurred by each mimetic species becomes proportionally more and more diminished the larger the number of indivduals over which the loss is distributed. Thus the resemblance being advantageous can be conceived to have been brought about by natural selection in the Müllerian mimicry in precisely the same way that it has been conceived to have been brought about in the Batesian mimicry. Whether it has actually been so brought about, is just the point about which there has been so much discussion; but if natural selection plays any part at all in species formation—and the writer still finds himself in the position of being without any other adequate theory—then a perusal of Prof. Poulton's paper, and the powerful arguments which he has marshalled therein, cannot fail to convince the unprejudiced naturalist that if natural selection was valid for Bates it is equally valid for Müller, and, further, that if natural selection is inadequate in either or both cases, then we have no theory of mimicry that will at all bear critical examination, and the whole body of facts remain as inexplicable as in pre-Darwinian times.

The method adopted by Prof. Poulton in the present paper is that of exclusion. He discusses all the alternative explanations which have been suggested, and finds them to be untenable when submitted to close analysis. There is thus left only the theory of natural selection The competing theories are all resolvable into three—viz. (1) external action of environment (2) independent development along similar lines by internal causes, and (3) psychical influence of predominating types of colour and pattern leading to the sexual selection of that type. The latter theory is not very likely to survive, although Mr. Darwin in 1872 wrote to the writer of this notice: "I do not feel at all sure that this view is as incredible as it may at first appear." It should be added that the said suggestion also came from Fritz Müller in a letter to Darwin. Rejecting for the present No. 3, the author deals at length with Nos. 1 and 2. Before marshalling the facts it is, however, considered necessary to insist that the resemblances herein dealt with are part and parcel of the general phenomenon of Protective Resemblance. This point is strangely put into the background, or altogether ignored, by the upholders of non-Darwinian theories of mimicry, and Prof. Poulton has done good service in bringing it well to the front again. It is surprising that the two sets of facts, viz. resemblance to environment and resemblance to other living species, should be dissociated, in spite of the circumstance that Bates and Wallace and most writers on the subject since have distinctly recognised the fundamental importance of grouping them together. It is, of course, inconvenient to the opponents of the Darwinian explanation to admit that resemblances to bark, leaves, twigs, &c., which are so well explained by natural selection, should be of the same order as a set of resemblances for which that explanation is regarded as indequate. And even if it is allowed that protective resemblance and the old (Batesian) mimicry are due to natural selection—as some of the speakers seemed to admit in the discussion of 1897—the extension to the newer (Müllerian) mimicry is opposed by either ignoring or denying the facts, or by substituting untenable theories.

The original theory of Müller was limited in its application to certain butterflies (*Ituna* and *Thyridia*) which were not very remote in their kinship, but in which the superficial resemblance was too exact to admit of explanation by blood-relationship alone. In 1882 the writer of this notice, in a paper published in the *Annals and Magazine of Natural History*, ventured upon an extension of the Müllerian principle to whole groups of related and "protected" species in which a general similarity in the type of pattern and colouring prevails. The idea was that the abstract type of marking became associated with a knowledge of inedibility in the mind of insectivorous enemies. Five years later (*Proc. Zool. Soc.*, 1887), the author of the paper now before us made a further advance by extending the Müllerian principle to large groups of insects quite unrelated by affinity, and belonging, in fact, to different orders. It is only necessary to bring together an assemblage of species belonging to different orders, and having a general superficial resemblance among themselves, to constitute a presumptive case of "Müllerian association." If it can be shown that this group of species is for one reason or another more or less exempt from persecution as compared with non-protected species, the case would at once become Müllerian as distinguished from Batesian. It is, of course, doubtful in many cases to which class a particular example of mimicry may belong. The result of the recent work of Poulton, Dixey and Mayer is to make it appear probable that the Müllerian principle is of more widespread importance in nature than the older principle of Bates.

Since the superficial resemblance of insects belonging to distinct orders, such as a moth to a wasp or beetle, a beetle to an ant, and so forth, cannot have been aided at the outset by blood-relationship, the result in all cases where the association is Müllerian, whether attributed to natural selection or to any other cause, can only have been brought about by a process of convergence. The essence of the Müllerian principle also is that the so-called protected species are subject to a certain percentage of extinction, and the resemblance which we now find among them is accordingly advantageous, in the same sense that a distasteful caterpillar is gorgeously coloured according to Wallace's well-known theory. For this reason Prof. Poulton prefers to limit the term mimicry to the Batesian principle; the Müllerian cases are described

in the present paper as "common warning colours, and the author proposes for them the term *synaposematic*.

Not the least satisfactory feature of the present summing up of the position by Prof. Poulton is the distinct convergence of the evidence in favour of the natural selection theory which has been accumulated since 1879. The sacrifice of a certain percentage of individuals to the inexperience of their enemies was an assumption on Müller's part, and the present writer well remembers pointing out in a letter to that eminent naturalist that his case would be enormously strengthened if he would make observations on the spot. The result was a long series of a distasteful *Acraea*, collected by Müller in order to show that bird-pecked wings were of frequent occurrence. Much evidence of the same kind has been since obtained, and a most valuable series of experiments conducted by Mr. Finn, in India, during the years 1895-96-97, and published in the *Journal* of the Asiatic Society of Bengal, have led that author to the conclusion that unpalatable forms are by no means altogether free from attack.

It must be further borne in mind that in 1879 the question of the non-transmission of acquired characters had not been brought into prominence. It was tacitly assumed in the theory of Bates that a knowledge of edible and inedible types could be transmitted by heredity. It is remarkable that Müller, by virtue of his hypothesis, should have unconsciously challenged this tacit assumption by suggesting that young birds had to learn by experience, and did not derive their knowledge of eatable and distasteful forms by heredity. The whole tendency of Prof. Lloyd Morgan's work of late years has been to confirm this suggestion by actual observation and experiment; and Mr. Finn, also, in summing up his results, states that "each bird has to separately acquire its experience, and well remembers what it has learned." Thus the Müllerian theory of 1879 has now been placed on a psychological basis of well-ascertained facts.

Those who still believe that common warning colours can be explained by internal or external causes, as defined in the present paper, will, we imagine, find the ground crumbling away from beneath their feet if they will seriously weigh the arguments set forth by Prof. Poulton. What series of external causes in nature are there, for example, which can so act upon an organism as to modify only those superficial characters which are required to bring about a resemblance to another form while leaving all other characters unmodified? To attribute such modification to independent evolution by virtue of innate tendencies or laws of growth or internal forces, appears to the writer to be substituting mysticism for scientific explanation. What external agencies can be conceived which shall, while acting without visible result upon the early stages of all kinds of insects, culminate only in a resemblance between the imagos? The external conditions of life are imposing themselves during the whole of the larval and pupal existence, and yet these forms remain quite distinct, while the imagos come forth at once with all their disguising characters perfected.

On considering again the undoubted fact that in many cases of mimicry and common warning colours the female only is affected, the inadequacy of any explanation depending on direct action of environment or internal evolutional "tendencies" becomes strikingly apparent. So also, as Prof. Poulton illustrates by a most remarkable set of examples, when insects of different orders resemble each other, the superficial similarity must necessarily be brought about by the most diverse kinds of modification of parts. To attribute such distinct and diverse modifications of form, directed towards a common end, to similarity of external forces or internal tendencies, seems to the writer to be a straining of hypothesis beyond any degree of rashness attributed to the supporters of natural selection. What natural agency can be imagined that will account for the production of a similar colour in two or more species—in one form by developing pigment, and in another by developing striation of surface, so as to produce the same chromatic effect, excepting selection which works only for advantageous results irrespective of means? Even within the same order, where the resemblances might be more reasonably supposed to be due to similarity of external conditions, the likeness is superficial only, and is brought about by the most diverse means. There is apparently no chemical relationship between pigments which produce the same visual effect in mimetic butterflies of different families. A visual resemblance is required only by natural selection; external and internal causes have been incompetent in such cases to modify the more deeply concerned physiological processes so as to produce similarity of appearance by identity of pigment. Such a character as transparency of wing, also, is shown to have been attained by several distinct methods; by reduction in the number of scales, by reduction in their size, by loss of pigment, by being set up on edge instead of lying flat, and so forth. Any common set of forces, external or internal, which can bring about the same result, viz. wing transparency, by such diverse methods is simply inconceivable.

We have given only a few illustrations of the arguments which the author makes use of in this paper to dispose of the theories which have been advanced by way of substitutes for natural selection. As Prof. Poulton says in conclusion: "The review of the whole subject during the past thirty-six years increases our confidence in the theories of Bates and Fritz Müller, while it disposes of all alternative hypotheses."

It should be added that many new examples of mimicry and common warning colours—some of them of the most striking character—are given in the paper. More particularly will English entomologists be interested in the resemblance of the young larvæ of *Stauropus fagi* to an ant, and of the similarity in appearance and habit of the young larvæ of *Endromis versicolor* to saw-fly larvæ.

R. MELDOLA.

## PROFESSOR CHARLES FRIEDEL.

FRANCE has lost one of her most distinguished chemists in the person of Prof. Charles Friedel, member of the Institute, who died at Montauban on April 20. He was born in Strassburg on March 12, 1832. His father was a banker; his mother was the daughter of Dr. Duvernoy, well known in his day as a scientific man. He distinguished himself so greatly in his studies that he took his degree of Bachelor of Science with special honours. Desiring to follow science as his profession he went to Paris, and gained the special esteem of M. de Sénarmont, who caused him to be appointed conservator of the mineralogical collections at the École des Mines. He worked in the laboratory of the distinguished chemist M. Adolph Wurtz, also a native of Alsace, at the École de Médecine. In 1856 he married Miss Kœchlin, by whom he had five children, one of whom, George Friedel, is known as a professor at the mining school of St. Etienne. Mrs. Friedel died in 1871, at Vernex, where she had retired during the Franco-German war; and her husband, who was shut up in Paris, knew nothing of the sad event until after the city capitulated. He was married again, in 1873, to Mlle. Louise Combes, whose father was a member of the Institute of France, and who, with their son and a large circle of relations, now mourn his recent decease. To return to his professional distinctions: in 1869 he became Doctor of Science; two years after he received a high appointment at the École Normale Supérieure. In 1876 he became Professor of Mineralogy at the Faculté des Sciences, at the Sorbonne; and in 1878 he received the

distinguished honour of membership of the Institute (Academie des Sciences). In 1884 he took the position of his late master, Prof. Wurtz, in the chair of Organic Chemistry at the Sorbonne. His merits were fully recognised in this country. In 1876 he became a foreign member of the Chemical Society, and four years later he received the Davy Medal of the Royal Society. In 1894 he made one of his rare visits to England to receive the degree of D.C.L. of Oxford University, an honour which he acknowledged as a great encouragement.

His influence on the advance of science was of a two-fold character: as a teacher, and as an original investigator. He was not known as a popular lecturer or writer upon science; but he had the happy faculty of infusing the love of science into the minds of the large number of students who attended his professorial lectures or worked in his laboratory. This result was no doubt greatly enhanced by the respect and personal attachment with which he was regarded. The advancement of education was in fact one of the objects of his life. This was evidenced by the successful efforts he made in promoting the École Alsacienne in 1874, which, to use his own words, was "designed to react against the exclusively literary and formal instruction, and directed in a Protestant and Christian spirit, without having any denominational colour." Its aim was to develop in each scholar the faculties which belong to him, and to arouse a spirit of observation and scientific curiosity. Natural science has, of course, an honoured place in the curriculum. He watched over this school with great interest, and helped to make it one of the best in the capital of France. The technical side of science also engaged his attention; and he had a large share in founding at Paris, three years ago, a laboratory of practical chemistry applied to industry, at the Sorbonne, and to which he gave special attention. He was one of the founders of the French Chemical Society. It is said also that the French Association for the Advancement of Science owes its origin to his suggestion; at any rate he came to the meeting of the British Association at Brighton in 1872 to learn the details of its working, for the benefit of the French Association which was to be inaugurated at Bordeaux in September of that year. The two Associations, though very different in their constitution, are carried on in much the same manner. M. Friedel generally took an important part in the French Association's annual meetings. In the last of the numerous letters that I received from him, he made reference in hopeful terms to the approaching meetings of the two Associations at Dover and Boulogne in September next, and to the efforts which were in contemplation to bring together the savants of the two nations.

Throughout the whole of his career he carried on original research, the results of which are published in about one hundred papers communicated to the Academy of Sciences and other learned societies. Some of these refer to the artificial formation of felspar and albite, crystallised quartz and other minerals, and to the dimorphism of zinc blende; but by far his most important work has reference to the carbon compounds, and the long controversies which raged over the question of their constitution, and how it should be expressed. His first paper seems to have been a contribution, in 1857, bearing on the constitution of acetone. This was followed by others on lactic acid, glycerine, propylene and other members of the three-carbon family. The relation of these bodies one to another, and to their isomers, led to much fruitful controversy. To him, in fact, is due in great measure the introduction of the new views of atomic valency, of which the chief apostles were Cannizzaro and Kekulé. In France these ideas were not readily received; the chief advocacy of them came from the laboratory of Wurtz, and although Friedel had not the enthusiasm and brilliancy of the master, his expositions and arguments were wonderfully clear, and his experiments in support of them very convincing. Among these was the production, in conjunction with Ladenburg and Crafts, of a number of compounds of silicon and titanium showing the quadrivalence of these elements and their chemical analogy with carbon. In this way they broke down the barriers between organic and inorganic chemistry, and showed the generality of the laws of chemical combination. During these researches he was fortunate in discovering a new method, by means of chloride of aluminium, of bringing about the synthesis of organic compounds, often producing hydrocarbons of a highly complex character.

With the rapid advance of chemical knowledge, especially in the organic department, and the gradual growth of chemical theory, the nomenclature was found to be inexact and often misleading. Hence in 1892 a congress of chemists was held in Geneva to revise the nomenclature. Leading representatives of chemical science from many countries met together, and Friedel was appointed president. The recommendations arrived at were published in Wurtz's Dictionary of pure and applied chemistry, which was carried on under the direction of Friedel.

But he did not confine his work to scientific teaching and investigation. Born in a Protestant family, he seems from his youth to have adopted the religious principles in which he was brought up. He sympathised with all Christian, philanthropic or patriotic movements of his country, and took an active part in many of them, especially those that related to the welfare of young men. Those of us who knew him intimately will feel disposed, like the President of the Academy in announcing his death, to dwell not so much on his great scientific achievements as on the amiability and uprightness of his character and on the moral worth of his personality.

J. H. GLADSTONE.

## *CHARLES NAUDIN.*

CHARLES NAUDIN, whose contributions to science extend over the last sixty years, died on March 19, at Antibes, at the age of eighty-four. A systematist by his studies of the orders *Melastomaceae* and *Cucurbitaceae*, a biologist by his work on hybrids, he is perhaps best known by many contributions to economic botany.

The bravery with which he met the hardships of his life wins admiration. His father, a schoolmaster, ruined himself; his mother died when he was but eight years old. At Montpellier, while working for a degree, he served as usher in small establishments: the degree gained, he became a teacher at Château-Chinon, then at Cette. In 1839 we find him at Paris earning his living by teaching, by copying commercial letters, and lastly as a gardener at the Jardin des Plantes, burning the midnight oil in order to obtain his licentiate in 1841 and the degree of Doctor of Science in 1842.

After helping Saint-Hilaire with his flora ot South Brazil, Naudin became professor of zoology at the Collège Chaptal. But, when success seemed assured, severe facial neuralgia and an incurable deafness, worse than the neuralgia, cut him off from free communion with his fellow-men. Forced back from his course, he applied himself again to herbarium-work, and the study of the *Melastomaceae*—an order richly represented in Brazil—gave him employment till 1849.

Five years later Decaisne made him his aide-naturaliste, and under his stimulus Naudin commenced the experiments on hybrids which secured his reputation. Darwinism had disturbed science; and Decaisne, who, like others, was asking what are species, had commenced to experiment on variability with admirable patience by growing pears from seed. Naudin chose the Gourd

family for like experiments on the variability of hybrids, in doing which he came face to face with difficulties in classification needing the eye of a systematist. How these were met, Sir Joseph Hooker, whom he helped in dealing with this order for the *Genera Plantarum*, and others testify. It is clear that if he multiplied names unduly, he still grouped naturally and truly the allied forms. In the question of hybridity he emphasised abundantly the fact that hybrids frequently have a varying measure of fertility, stating at the same time that in varying they return to the parent forms, and for that reason fail to establish their race—a contention which led to a long controversy.

At this period his work as a gardener came into fruit: the *Manuel de l'amateur des jardins*, and a connection with the *Revue Horticole*, *Flore des Serres* and *Le bon Jardinier* testify to it. But the neuralgia increased, and drove him to seek an asylum away from work in the Pyrenees, whence in 1878 he was called to take charge of the experimental station known as the Villa Thuret at Antibes.

There, in the pleasant climate of the Mediterranean shore, he experimented in the acclimatisation of such plants as were suitable. Algeria, among French Colonies, needed improved cultivation; and the exigence of Algeria called his attention to the vegetation of dry countries. From Australia he grew *Eucalypti* and *Chenopodiaceae;* from South Africa he experimented with *Acanthosicyos;* and the flowering and fruiting and hybridisation of palms interested him strongly. To these experiments on Australian plants is doubtless due his connection with Sir Ferdinand von Mueller, which led to a joint *Manuel de l'Acclimateur*.

This must suffice to indicate the direction of his work—work for which the French-speaking people feel a keen gratitude. To us, it is interesting to recall that a few of his later notes appeared in our language in the *Gardeners' Chronicle*, while two of his earlier papers were considered of sufficient importance to merit translation.

I. H. B.

## THE NEW BUILDINGS AT SOUTH KENSINGTON.

THE foundation stone of the new extension of the Art Museum at South Kensington was laid by Her Majesty the Queen yesterday. When completed, the Museum will be one of the most imposing structures in London, so far as size is concerned. It will have a frontage on Cromwell Road of 700 feet—almost precisely the same frontage as that of the Natural History Museum—and in the Exhibition Road there will be a frontage of 300 feet. The area of the new buildings will be equal to the whole of that covered by the existing Museum, including the temporary sheds on the west side of Exhibition Road.

The Art Museum thus completed is to be called the Victoria and Albert Museum.

The commencement of the new buildings does not directly concern us except that they are complementary to other buildings to be provided for Science on the ground facing the Imperial Institute. It has generally been understood since the Report of the Duke of Devonshire's Commission, which sat about a quarter of a century ago, that a Science Museum was to be built upon this ground. This being so, the building scheme might appropriately have included an Albert Museum for Science as well as a Victoria Museum for Art. But no provision has been made for such a new Science Museum.

According to the *Times*, the centre of the building which it is proposed to place opposite the Imperial Institute will be occupied by the Science Library, and in the plan given by the *Times* the proposed buildings are called "Royal College of Science." But this is not so. The remainder of the frontage will be taken up by chemical and physical laboratories alone; the other departments of the Royal College of Science—astronomical physics, geology, biology, mechanics, mining and metallurgy—will apparently be left in the same unorganised condition as exists at present. It is indeed generally imagined, and it may even be the view of the Chancellor of the Exchequer, that the new buildings are to accommodate all the departments of the Royal College of Science.

We read, for instance, in Tuesday's *Times*:—

"As regards the Royal College of Science, it will, as already indicated, occupy a position directly facing the Imperial Institute. It is to be of the same length as the Institute, and, in the interests of architectural harmony, it will reproduce several of its leading features. The College will be recessed from the road in the same way; the main entrance of the one will be opposite that of the other, and will be so rounded that between the two a large circular space will be left—in the centre of which a statue may be erected later on—the circle being flanked by the great buildings on each side. The domes or lodges at each extreme of the Imperial Institute will be repeated at corresponding points of the College, and the respective sets connected by a screen across the roadway, thus facilitating passage from one side to the other. The new College of Science will also form a front to the present Science Museum buildings, but there is no idea of the College forming in itself an additional "museum" in the recognised sense of that term. It will rather be devoted to strictly educational purposes, the right wing being occupied by the physical side of the College and the left by the chemical department, while the great laboratories and lecture theatres are to be in the rear, the whole being, further, in direct connection with the present Science Museum."

We repeat, the new so-called "College of Science" will represent only a small portion of the College. That the teaching of some of the subjects now carried on in buildings almost half a mile apart, gains nothing from the new scheme, might perhaps have been borne if it were perfectly certain that ultimately all the teaching would be brought together. But unfortunately this is now very much more unlikely than it has ever been before, unless the Science Museum is to be encroached upon, and its future possibilities of extension for ever wrecked; and the more the architectural effect is to be enhanced by recessing the new buildings from the road, the more, naturally, will the space difficulty be increased for College and Museum alike. We have heard that the plans prepared by the Professors of the Royal College themselves some years ago left the central portion clear primarily for the Museum suggested by the Duke of Devonshire's Commission, the chemical and physical laboratories having their frontage along Prince's Gate. That scheme was far preferable to the present one, so far as providing for the other requirements of both College and Museum are concerned.

In any case it must be acknowledged that the building of the chemical and physical laboratories is only a first step. We shall be glad to know that the future has been considered; and that there already exists a plan showing the condition of things when subsequent stages have been reached, even up to the final one. But we very much doubt whether it has been any one's business to consider any of these things, and responsibility is divided among so many departments that it is scarcely to be wondered at if the future has never been considered at all. But there is one thing greatly to be feared, and it is this. Not only does the plan to be carried out leave the greater part of the teaching in a chaotic state with no chance of betterment while the new buildings are going on; but when they are completed, some future Chancellor

of the Exchequer may decline further aid on the ground that no representation was made in the present year pointing out the exact state of the case.

It is apparently one of the prices we have to pay for the long neglect of Science in this country, and its small representation among those in political office, that so many arrangements touching our scientific institutions give rise to a hopeless feeling among those who are familiar with both the history and the facts connected with them.

## *NOTES.*

M. PRILLIEUX has been elected a member of the Paris Academy of Sciences, in succession to the late M. Naudin.

WE regret to see the announcement of the death of Sir Frederick McCoy, K.C.M.G., F.R.S., Professor of Natural Sciences in the University, Melbourne.

MR. W. H. PREECE, C.B., F.R.S., has accepted the presidency of the eighteenth Congress of the Sanitary Institute to be held in Southampton from August 29 to September 2.

THE foundation stone of a museum of Oceanography was laid at Monaco on April 25. The museum will contain the collections made by the Prince of Monaco during the expeditions of the yacht *Princess Alice*. It will contain not only exhibition rooms, but also laboratories for the use of men of science who wish to work upon the collections.

DR. J. BUCKLEY BRADBURY, Downing Professor of Medicine in the University of Cambridge, will deliver the Croonian lectures of the Royal College of Physicians of England in June, on "Some Points in Connection with Sleep, Sleeplessness, and Hypnotics."

WE learn from the *Botanical Gazette* that the Museum and laboratory building in the New York Botanical Garden is making fair progress towards completion. It is now entirely enclosed, and the partition walls and other rough interior work are nearly finished. It will probably be ready for occupancy late in the spring.

THE Department of Science and Art has received through the Foreign Office an intimation that the Ghent Horticultural Congress has been postponed from June 3 to July 8.

THE projected expedition of the Duke of the Abruzzi, nephew of King Humbert, to the North Pole is exciting great interest in Italy. A Reuter telegram from Rome states that the Duke, who will be accompanied by three officers of the navy, two sailors, four mountain guides, ten Norwegian sailors, and an Eskimo, will embark about the middle of June at Laurvig, Norway, whence he will proceed to Franz Josef Land, trying to attain as northerly a point as possible. The party will winter in the most northerly port attainable, and will spend enforced leisure in making scientific observations and preparing revictualling stations. In the spring the Duke and his companions will proceed towards the North Pole on sledges drawn by dogs, 120 of which he will embark at Archangel, or, if necessary, in a balloon. The expedition takes two balloons. If all goes well, the Prince will be away some eighteen months. The ship in which the Duke of the Abruzzi will sail is called the *Stella Polare*.

THE Rev. T. Neville Hutchinson, whose death occurred on May 6, did much to advance the interests of science by his work some years ago as senior science master at Rugby. Forty years ago Rugby was the only public school in which science was taught at all. Harrow and Eton followed, though not with the same liberality as Rugby, where a few years later a special suite of lecture-rooms and laboratories was devoted to science. It was Mr. Hutchinson who reorganised the science work at Rugby in 1870, and in the first volume of NATURE he described the new laboratories and other buildings erected there for purposes of scientific instruction. Mr. Hutchinson was born in 1826. He was second master at King Edward's School, Birmingham, in 1860–65, and science master at Rugby from 1865 to 1883, when he became vicar of Broadchalke, Wilts. He resigned his vicarage last October, and was made Canon of Salisbury. He was a gifted teacher and lecturer, and old Rugbeians will sincerely regret to learn of his death.

THE death, shortly before completing his sixtieth year, of Mr. Philip Thomas Main, of St. John's College, Cambridge, is announced in the *Athenaeum*. Mr. P. T. Main published "An Introduction to Plane Astronomy" for University use in 1865, and also assisted his father, the Rev. Robert Main, who was for twenty-five years Chief Assistant at the Royal Observatory, Greenwich, and afterwards for eighteen years Radcliffe Observer at Oxford, in his large work on "Practical and Spherical Astronomy," which appeared in 1863. Subsequently he turned his chief attention to chemistry, and for many years held the post of superintendent of the laboratory at St. John's College.

THE Council of the British Medical Association desire to remind members of the profession engaged in researches for the advancement of medicine and the allied sciences that they are prepared to receive applications for grants in aid of such research. Applications for sums to be granted at the next annual meeting must include details of the precise character and objects of the research which is proposed, and must be made on or before June 15 in writing addressed to the General Secretary of the Association. The Council are prepared to receive applications for one of the three research scholarships which is vacant, of the value of 150*l.* per annum, tenable for one year, and subject to renewal by the Council for another year. Applications may also be sent in for a scholarship of 200*l.*, for the study of some subject in the department of State Medicine, in memory of the late Mr. Ernest Hart.

THE thirtieth general meeting of the Institution of Mining Engineers will be held in London on May 25. Among the papers to be read, or taken as read, are the following:—Presidential address, by Mr. J. A. Longden; alternating currents and their possible applications to mining, Part i., by Mr. Sydney F. Walker; metric weights and measures, by Mr. J. Emerson Dowson; Petroleum in Burma, by Dr. Fritz Noetling; mineral resources of Vancouver and adjacent islands, British Columbia, by Mr. Wm. M. Brewer; and a new process of seasoning and preserving timber and other fibrous substances by means of electricity, by Mr. H. Baillie-Weaver.

ARRANGEMENTS are being made for a visit of the Institution of Electrical Engineers to Switzerland in September next. As at present arranged, members will visit the Rheinfelden works on Saturday, September 2, will proceed on the same day to Zürich, and will remain there until September 6. During this time visits will be paid to various industrial works, and to certain power stations and tramway and lighting installations in the district, including, it is hoped, a visit to the Schaffhausen works. The members will then proceed to Lucerne, and, after inspecting the street railways of that town and, if time permit, the Rathhausen works and the Stansstad-Engelberg Railway, will travel, *via* the Brünig Pass, to Interlaken. Here opportunity will be given for visiting both the Jungfrau Railway (*via* the Wengern Alp route) and the Burgdorf-Thun Railway, as well as other places of electrical interest in the neighbourhood; and the visit will end on Saturday, September 9. The annual

conversazione of the Institution will be held at the Natural History Museum, South Kensington, on Thursday, June 15.

A DISASTROUS explosion occurred on Friday at the Kurtz's Chemical Works, belonging to the United Alkali Company, St. Helens, Lancashire. The force of the explosion was so great that it was felt not only at Prescot and Haydock, about four miles away, but also in the suburbs of Liverpool and at Leigh, which is twelve miles distant. Mr. Stewart, managing director of the United Alkali Company, says that about 10 a.m. he saw that the side of the chlorate of potassium crystallising vessel was on fire. These vessels are of wood, but lined with lead, and there were many of them in the crystallising house. The officials were promptly warned, and they brought up the fire extinguishing appliances; but in ten minutes the fire had reached the store containing a considerable quantity of chlorate. The men were instantly sent from the works. When the flames reached the chlorate store a violent explosion resulted, and the refining and the grinding plant was completely destroyed. This was followed by another explosion, which reduced the chemical works to ruins.

FROM the ninth report of the British Association Committee on photographs of geological interest, we learn that the total number of photographs now in the collection is two thousand and one. Amongst the more noteworthy additions referred to in the report may be mentioned an interesting set from Arran, Cumbrae, Ailsa Craig, and the Fifeshire volcanic necks, together with some from Westmoreland and Banffshire; a set from Glenroy and the Scottish Highlands; large series from Westmoreland and Yorkshire, many of them representing glacial phenomena, unconformities, and faults; pleistocene deposits; dykes in the new red sandstone; silurian, cambrian, and igneous rocks of the Midlands; raised beaches in Devon ridge; oolites; a set from the Rochdale district; a set from the Isle of Man; and one of typical specimens of rocks and microscopic slides. The Committee call attention to the small amount of work yet done in such districts as N. and S. Wales, the Yorkshire Dales and Moors, the Malverns, the districts round Oxford and Cambridge, Cornwall, the Southern Uplands, the Central Valley of Scotland, and Central and Southern Ireland.

THE *Société Internationale des Électriciens* have just published an account of a tour, made by *L'École supérieure d'Électricité*, to investigate the power-transmission systems at certain stations in Switzerland. In this tour, of only one week, the students collected a very useful amount of information with regard to the hydraulic machinery and electrical plant. They had special facilities for examining the systems, and in many cases they obtained drawings of details of construction. These drawings now form part of the account of their excursion. We notice with particular interest the description of various methods for regulating turbines and electro-motors. After the various hydraulic installations, the methods of distribution are considered. A chapter on electric traction follows, and then an account of the works of Brown-Boveri and the Oelikon factory. Lastly, there is a note on the manufacture of calcium carbide. Similar tours might with advantage be arranged by English technical schools. In their devotion to "*la belle science*" the railway companies allowed a reduction of fifty per cent. on all fares. Similar reductions might be allowed by British railway companies.

THE *Transactions* of the Swedish Academy of Science, No. 7, 1898, contains a paper, in English, by Mr. John Rhodin, on the theory of storage cells, dealing especially with the phenomena attending the cessation of current as depending upon the concentration of the electrolyte and the amount of active material.

MR. J. ELSTER and Mr. H. Geitel have contributed a joint paper to *Terrestrial Magnetism* of March last, relating to a continuation of their important researches on the electricity of rainfall, perhaps the most difficult of all electrical phenomena; the subject is, in fact, so complicated as to allow but little prospect of establishing fixed rules of the processes concerned. Their previous investigations referred more particularly to the determination of the sign of the potential, while the present paper deals with the measurement of the amount. To carry this out satisfactorily an apparatus is required which will show, in rapid succession, both high differences of potential of several thousand volts as well as small differences of, say, 100 volts, while the capacity of the apparatus must be so small as to exhibit rapid variations of the field from positive to negative extremes. The apparatus devised for the purpose is illustrated and minutely described, and the results obtained, while confirming their previous determinations of the sign of the electricity during atmospheric precipitation, show that this may bring with it very considerable amounts of both positive and negative electricity.

THE Deutsche Seewarte has published the eighth volume of its valuable meteorological observations made at foreign stations. It includes some places in Labrador, from which observations have been regularly published since 1883; these are specially important, because many barometric minima travel across Labrador from Canada to the Atlantic Ocean. We are glad to see that the Seewarte intends to increase the number of foreign stations, by including others which do not belong properly to German Protectorates or Colonies. The present volume contains observations from Mogador, Campinas (Brazil), and Fray Bentos (Uruguay). The observations are in all cases carefully made by German officials, or residents, and in nearly all instances the instruments have been supplied by, or through, the Seewarte, and are therefore thoroughly trustworthy.

A REPORT by Prof. David Hansemann, of Berlin, on the brain of Hermann von Helmholtz, is referred to in the *British Medical Journal*. The great physicist died of apoplexy on September 8, 1894, at the age of seventy-three. The circumference of the head was 59 centimetres, that of the skull 55 centimetres. The breadth of the skull was 15·5, and its length 18·3 centimetres. The cephalic index was therefore 85·25, showing a broad head. Helmholtz's head was about equal in size to that of Bismarck, and rather smaller than that of Wagner, both of whom had big heads. On the other hand, Darwin's head was only 56·3 centimetres in circumference. The weight of the brain, with its blood, was 1700 grams, without the blood 1440 grams, being about 100 grams heavier than the average human brain. The sulci were very deep and well marked, especially in those parts of the brain which Flechsig has shown to be concerned in associations. The frontal convolutions in particular were deeply cut by very numerous sulci. Helmholtz, like Cuvier, was somewhat hydrocephalic in youth. It has been maintained by Perls, and also by Edinger, that hydrocephalus in early life may be an advantage, inasmuch as it enlarges the skull and gives the brain space for growth. Prof. Hansemann appears to be of the same opinion.

A MEMOIR on the geology of the country around Carlisle, by Mr. T. V. Holmes, has just been issued by the Geological Survey. The country described is almost wholly covered with superficial deposits, boulder clay and gravel, peat, alluvium and blown sand. As it has been customary to issue two editions of the Geological Survey map, one with, and the other without drift, it may be inferred that considerable difficulty was felt in interpreting the "solid" geology of this region. The concealed rocks consist largely of the New Red Series, St. Bees sandstone, gypseous shales, Kirklinton sandstone, and Stanwix shales—with an outlier of Lower Lias, but no evidence of the

Rhætic beds. The precise underground extent and the relations of the subdivisions of the New Red Series have been the subject of considerable difference of opinion, but the evidence obtained from borings and river-cliffs is clearly stated by Mr. Holmes.

MR. WILLIAM H. DALL makes some remarks (*Proc. Acad. Nat. Sc. Philad.*, January 1899) on the celebrated Calaveras skull, which was found more than thirty years ago in a bed of gravel 132 feet below the surface of the uppermost lava-bed of Bald Hill, one of the "table mountains" of Calaveras County, California. Mr. Dall was in California at the time of the discovery, and records his evidence in favour of its genuineness.

ONE of the best-known examples of change of level during earthquakes is that of the great Kutch earthquake of 1819, when a large portion of the Rann of Kutch was depressed and immediately flooded by the sea, while at the same time a long mound was seen, which is known as the Allah Bund or Dam of God. With regard to the depression there can be no doubt; but the character of the elevation, whether real or only apparent, is not so certain. The former view, supported by Lyell, was held until 1872, when Mr. A. B. Wynne (followed by Prof. Suess) argued that the Allah Bund represented merely the comparatively steep slope connecting the area which had been depressed from that whose level was unchanged. In a paper in the *Memoirs* of the Geological Survey of India (vol. xxviii., pt. i., 1898), Mr. R. D. Oldham favours the older view, and presents a map and section (made by Captain Baker in 1844), which show that there was an actual upward slope of the ground from the plain on the north to the southern scarp of the Allah Bund.

EFFORTS to determine the molecular structure of certain crystals have been made by means of etching them with hydrofluoric acid or other reagents. The importance to petrographers of etch-figures in the investigations of amphiboles (hornblende, &c.) forms the subject of an elaborate paper by Mr. R. A. Daly (*Proc. Amer. Acad. Arts and Sciences*, March 1899).

THE New South Wales Department of Public Health has just issued a report, by Mr. Frank Tidswell, principal assistant medical officer of the Government, on protective inoculation against tick-fever. The colony, in view of the ravages wrought by this disease in Queensland, are making strenuous efforts to prevent a repetition of the disaster in New South Wales. The subject has been very carefully investigated by American authorities, and the results obtained by Mr. Tidswell confirm those previously obtained in America. It appears that more or less efficient protection from the disease can be procured by inoculating the blood of animals which have recovered from the fever, whereby the disease is produced in a mild form. Such artificial production of the disease is sometimes attended with considerable risk to the animal treated. Experience has shown, however, that it is principally older cattle which succumb, although, curiously, bulls, whether young or old, are extremely susceptible to tick-fever, and the greatest care has to be exercised in carrying out the inoculations. The period over which immunity lasts has not, so far, been accurately determined, but immunity is acquired as early as six days after the subsidence of the fever. The disease appears to be widely distributed, having been identified in America, Jamaica, the Argentine Republic, South Africa, Roumania, and Java. It was first described by American investigators in 1893, and was called Texas or Southern cattle fever, in consequence of the locality where it was originally discovered. In Australia it is usually known as tick-fever, owing to the part played by ticks in transmitting what is now known to be the real cause of the disease, the micro-organism called by its discoverers *Pyrosoma bigeminum*. At present the protective inoculation system is in a very elementary stage, but it is confidently anticipated that with improved methods, based upon further researches, a very valuable measure will be introduced for effectually compassing this ruinous pest.

THE *National Geographic Magazine* for April contains an account, by Mr. Walter D. Wilcox, of two expeditions to the headquarters of the Saskatchewan. The two main branches of the river start from the same ice-fields in the high Rockies, and after diverging several hundred miles unite in the plains 900 miles from the source. Mr. Wilcox reached the region of the sources by ascending the Bow River from Laggan, and amongst other geographical results of interest discovered a pass from the Saskatchewan to the Athabasca.

A NOTE on a harpoon-head found in a whale in the Bering Sea in August 1890, is contributed to the *National Geographic Magazine* by Mr. W. H. Dall. Marks on the iron showed that it belonged to the American whaler *Montezuma*, which was engaged in the North Pacific about the years 1850–54; the whale must, therefore, have carried it for between thirty-six and forty years. Mr. Dall also gives some observations by Captain E. P. Herendeen with regard to whales supposed from similar evidence to have made the north-east or north-west passage.

THE *Comptes rendus* of the Paris Geographical Society (1899, No. 2) contain a note by M. Jules Richard on a series of nine short land excursions made from the Prince of Monaco's yacht *Princess Alice*, during her Arctic cruise in the summer of 1898. A number of observations, chiefly zoological, were made from various points and islands in the neighbourhood of Spitsbergen. Photographs taken at Bear Island, Hope Island, and Sassen Bay are reproduced.

DR. HAGBART MAGNUS, of Bergen, contributes an important paper on the population of Norway to the *Zeitschrift der Gesellschaft fur Erdkunde*, a summary of a larger memoir already published in the Norwegian language. The distribution of centres of population is discussed with reference to the geography of different parts of the country, the inhabited districts being separated into coast regions, fjord regions, and valley regions. The transition from each of these into the uninhabited regions is carefully examined, and the development of unfavourable conditions of various kinds traced. A sketch-map, preliminary to an attempt to construct a map showing the density of population in southern Norway, is appended.

IN an article in the *Botanical Gazette* for April, Prof. W. F. Ganong describes the following appliances for the elementary study of vegetable physiology in use at Smith College, Northampton, Mass.:—A temperature stage, a clinostat, a recording auxanometer, an osmometer, a respiration apparatus, a germination box, a root-pressure gauge.

THE annual report of the Royal Botanic Gardens, Trinidad, for the year 1898 affords evidence of steady work done by the superintendent, Mr. J. H. Hart, and his staff, in the cultivation of economic plants, in the herbarium, and in exchanges with other parts of the world. A newly introduced species of cacao, *Theobroma pentagona*, may possibly be of commercial importance.

IN a paper in the *Biologisches Centralblatt*, Dr. L. Jost argues, from the remarkable tendency in *Linaria spuria* towards the sudden production of anomalies in the flower, which might be regarded as establishing new species, or even new genera, that the differentiation of species and genera may have been a much more rapid process than has generally been assumed by evolutionary naturalists.

WE have received two interesting reprints from the *Memoirs* of the Boston Society of Natural History for 1899:—Localised Stages in Development in Plants and Animals, by Mr. R. T.

Jackson; and the Development, Structure, and Affinities of the Genus *Equisetum*, by Mr. E. C. Jeffrey. The former paper is occupied by illustrations of the law laid down by the author, that throughout the life of an individual stages may be found in localised parts which are similar to stages found in the young, and the equivalents of which are to be sought in the adults of ancestral groups. The investigations of Mr. Jeffrey lead him to the conclusion that the Equisetales are nearly allied to the Lycopodiales, and that they are descended from the Sphenophyllales, with which they agree closely in all important particulars except the structure of the stele.

MR. MURRAY has in preparation, and will publish as soon as possible, Sir William Crookes' reply to the many criticisms evoked by his address to the British Association last year.

THE monthly meeting of the Edinburgh Mathematical Society was held on Friday, May 12, when "The Treatment of Proportion in Elementary Mathematics" was discussed. Dr. Morgan, President, occupied the chair.

THE 143rd meeting of the Yorkshire Naturalists' Union will be held at Dent, on Whit-Monday, May 22, for the investigation of the valley of the Dee, the northern slopes of Whernside, Gragreth, Holme Fell, and the neighbourhood.

MESSRS. MARION AND CO. have just introduced a new hand camera—the Cut-film Swallow Camera—which has several commendable points. The camera takes thirty flat films, without notches, the size being the $\frac{1}{4}$-plate-$4\frac{1}{4} \times 3\frac{1}{4}$. Its weight loaded with thirty films is only 4 lbs. The lens is a single achromatic lens of the fixed focus type and good covering power.

A NEW section of the second edition of Prof. Ostwald's "Lehrbuch der allgemeinen Chemie" has been published by Mr. Wilhelm Engelmann, Leipzig. The pages included in this Lieferung extend from 605 to 828, dealing with chemical equivalents of the second order. Another section on the same subject will bring the second part of the second volume to an end. The third part of the second volume, which will conclude the work, will be concerned chiefly with special chemical dynamics. A supplement will be published dealing with advances made while the work has been passing through the press.

PROF. GATTERMANN, of Heidelberg, has added another to the list of silicon acids. The new compound, which he terms silicomesoxalic acid, is obtained by leaving the chloride $Si_3Cl_8$ in a platinum dish exposed to the air. Hydrochloric acid is evolved and the octochloride is slowly transformed into a white amorphous mass of silicomesoxalic acid to which the formula $HO.OSi - Si(OH)_2 - SiO.OH$ is ascribed. It is very unstable, and on heating decomposes with a flash. When quite pure and dry, a touch is sufficient to effect this change.

THE additions to the Zoological Society's Gardens during the past week include a Ring-tailed Lemur (*Lemur catta*, ♀) from Madagascar, presented by Mrs. Penn Curzon; a Common Badger (*Meles taxus*, ♀), British, presented by Mr. John N. Docwra; an Angolan Vulture (*Gypohierax angolensis*) from North-west Africa, presented by Staff-Sergeant Patten; a Hoary Snake (*Pseudaspis cana*), a Rough-keeled Snake (*Dasypeltis scabra*), two Rhomb-marked Snakes (*Trimenorhinus rhombeatus*), two Crossed Snakes (*Psammophis crucifer*) from South Africa, presented by Mr. J. E. Matcham; a Common Snake (*Tropidonotus natrix*), British, presented by Mr. E. C. Brook; two Common Marmosets (*Hapale jacchus*) from South-east Brazil, a Reticulated Python (*Python reticulatus*) from the East Indies, a Spiny-tailed Iguana (*Ctenosaura acanthura*) from Central America, a South Albemarle Tortoise (*Testudo vicina*) from the Galapagos Islands, deposited; two Crowned Lemurs (*Lemur coronatus*), born in the Gardens.

## OUR ASTRONOMICAL COLUMN.

PARTIAL ECLIPSE OF THE SUN, JUNE 7.—This eclipse will be visible at Greenwich and throughout Northern Europe and Northern Asia. The Greatest Eclipse will be visible in latitude 67° 18′ N., and longitude 99° 5′ W. of Greenwich, on June 7d. 18h. 34·0m.; the magnitude being 0·611 (sun's diameter = 1). The following table gives the details for British stations, Greenwich mean time being used in all cases except that of Dublin, where local mean time is taken.

| Station | Begins | Greatest Eclipse | Ends | Magnitude |
|---|---|---|---|---|
| | h. m. | h. m. | h. m. | |
| Greenwich ... ... | 16 42·8 | 17 17·4 | 17 53·4 | 0·188 |
| Cambridge ... ... | 16 43·2 | 17 18·6 | 17 55·5 | 0·197 |
| Oxford... ... ... | 16 42·8 | 17 18·2 | 17 55·1 | 0·200 |
| Liverpool ... ... | 16 43·8 | 17 21·5 | 18 0·9 | 0·233 |
| Edinburgh ... ... | 16 45·7 | 17 25·9 | 18 7·8 | 0·263 |
| Dublin... ... ... | 16 18·6 | 16 57·3 | 17 37·6 | 0·253 |

At Greenwich and approximately throughout the British Isles the contacts are as follows:—

| | | | | |
|---|---|---|---|---|
| Angle from North Point | First contact | 42° | towards the West | For *direct* image. |
| | Last ,, | 29° | ,, ,, East | |
| Angle from Vertex | First ,, | 6° | ,, ,, West | |
| | Last ,, | 70° | ,, ,, East | |

COMET 1898 *a* (SWIFT).—The following ephemeris is by Herr H. Kreutz, in *Astr. Nach.*, No. 3556:—

*Ephemeris for 12h. Berlin Mean Time.*

| 1899. | R.A. h. m. s. | Decl. ° ′ | Br. |
|---|---|---|---|
| May 18 | ... 22 34 21 | ... +43 42·9 | |
| 19 | ... 23 37 | ... 45 23·1 | ... 1·77 |
| 20 | ... 22 11 40 | ... 47 4·2 | |
| 21 | ... 21 58 20 | ... 48 44·5 | ... 1·79 |
| 22 | ... 43 29 | ... 50 22·7 | |

No information as to any observations of this comet has yet been received. The positions given above would indicate it to be moving to the north-east through Pisces; at the end of the month it will be about half-way between *γ* Pegasi and *β* Arietis, but after this it will probably be lost owing to its nearing the sun.

ROTATION PERIOD OF MARS.—Mr. W. F. Denning has recently secured some measures of the times of transit of the Syrtis Major (Kayser Sea), which in conjunction with observations made by him in 1884 and 1869 give a critical value for the period (*Observatory*, May 1899, p. 195). On February 4, 1869, the Syrtis Major was in mid-transit at 11h., while on February 14, 1884, when Mars was similarly situated with reference to the Earth, the transit occurred at 5h. 55m. Other transits were taken as February 15, 6h. 35m.; February 19, 9h. 5m.; February 22, 11h. 4m. Now, after another interval of fifteen years, the transit on March 7, 1899, occurred at 8h. 31m. The whole period between 1869 February 4, 11h. and 1899 March 7, 8h. 31m., comprises 10,987 days, 21 hours, 31 minutes, during which Mars has performed 10,710 rotations. The mean period during this interval thus becomes

24h. 37m. 22·70s.

This value is intermediate between those of Proctor and Bakhuyzen.

## *AN IMPROVED RESISTANCE-BOX.*

MESSRS. GAMBRELL BROS. have recently introduced a resistance-box of improved design, which gives promise of eliminating several of the disadvantages of the usual post-office pattern. Fig. 1 shows the appearance of the box with the cover removed to show the working parts. The coils, which hang vertically in the lower part of the box, are brought up to

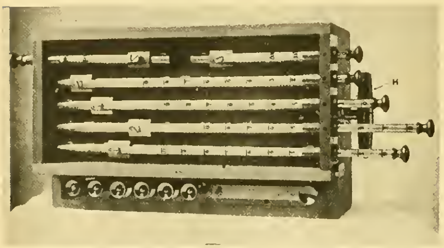

FIG. 1.—General view of the box, from above, showing the numbered slide rods, the contact shoes and the terminal studs of the coils. The handle (H) at the right is for clamping all the contact shoes simultaneously.

terminal studs (T) seen in Fig. 2, arranged in five rows, one of which, in two sections, forms the "ratios" used as two arms of the bridge. The upper surfaces of these studs are semicircular, fitting the concave surfaces of the sliding contact shoes (S). The four rows other than the "ratios" provided for thousands, hundreds, tens and units, reckoned from the side nearest the terminals and key. Each of these contact shoes slides with slight friction on a brass bar running the length of the box, and supported at each end by metal pillars held down by springs inside the box. To move the shoes from one stud to another other

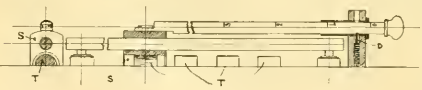

FIG. 2.—Showing construction of slider, spring contact bar, &c.

brass rods are attached, which slide through ebonite bushes on the end of the box. On these rods are engraved the figures giving the amount of resistance in use, the value of any particular resistance in circuit being indicated by the number showing just outside the ebonite bush. To ensure the contact shoe being properly fixed on the studs, a spring detent (D, Fig. 2) is provided under each bar, so that the resistances may be changed without the experimenter needing to watch the bar. All the bars being arranged to give the resistance required, it will be evident that its total amount can be read straight off at the end of the box, being given by the row of figures close to the four ebonite bushes. For example, the reading of the resistance in circuit, as shown in Fig. 1, is 2310. This is itself a great convenience, and will prevent any chance error in adding. As an additional help to maintaining the contacts as constant and perfect as possible, when the proper resistance has been found, all the four shoes are drawn tightly down on to the terminal studs by turning the handle H, seen under the ends of the rods in Fig. 1. This actuates a cam inside, which moves the small pillars at each end of the brass bars passing through the contact shoes. At the same time, the arrangement acts as a clamp, so that while the handle is turned the resistances cannot be changed. All the pillars are held down by springs, so that when not clamped by the handle H the sliding to and fro is accompanied by sufficient friction to keep the contact surfaces clean.

In consequence of the ingenious method adopted for reading off the figures, rendering access to the contacts themselves quite unnecessary, the whole of the system of studs and sliding bars is covered in permanently, so that they and the ebonite insulating block are kept free from dust and corrosion. The studs, being a considerable distance apart, should permit of a very high insulation resistance, while at the same time allowing a large surface contact between the shoe and the stud.

It will be seen that this new form of box has many advantages to recommend it to notice. The simplicity and rapidity of reading, its compactness, and its non-liability to deterioration, should cause it to find favour both in laboratory and testing-room experience.

## *TRANSPARENCY AND OPACITY.*[1]

ONE kind of opacity is due to absorption; but the lecture dealt rather with that deficiency of transparency which depends upon irregular reflections and refractions. One of the best examples is that met with in Christiansen's experiment. Powdered glass, all from one piece and free from dirt, is placed in a bottle with parallel flat sides. In this state it is quite opaque; but if the interstices between the fragments are filled up with a liquid mixture of bisulphide of carbon and benzole, carefully adjusted so as to be of equal refractivity with the glass, the mass becomes optically homogeneous, and therefore transparent. In consequence, however, of the different dispersive powers of the two substances, the adjustment is good for one part only of the spectrum, other parts being scattered in transmission much as if no liquid were employed, though, of course, in a less degree. The consequence is that a small source of light, backed preferably by a dark ground, is seen in its natural outlines but strongly coloured. The colour depends upon the precise composition of the liquid, and further varies with the temperature, a few degrees of warmth sufficing to cause a transition from red through yellow to green.

The lecturer had long been aware that the light regularly transmitted through a stratum from 15 to 20 mm. thick was of a high degree of purity, but it was only recently that he found to his astonishment, as the result of a more particular observation, that the range of refrangibility included was but two and a half times that embraced by the two D-lines. The poverty of general effect, when the darkness of the background is not attended to, was thus explained, for the highly monochromatic and accordingly attenuated light from the special source is then overlaid by diffused light of other colours.

More precise determinations of the range of light transmitted were subsequently effected with thinner strata of glass powder contained in cells formed of parallel glass. The cell may be placed between the prisms of the spectroscope and the object-glass of the collimator. With the above-mentioned liquids a stratum 5 mm. thick transmitted, without appreciable disturbance, a range of the spectrum measured by 11·3 times the interval of the D's. In another cell of the same thickness an effort was made to reduce the difference of dispersive powers. To this end the powder was of plate glass and the liquid oil of cedar-wood adjusted with a little bisulphide of carbon. The general transparency of this cell was the highest yet observed. When it was tested upon the spectrum, the range of refrangibility transmitted was estimated at thirty-four times the interval of the D's.

As regards the substitution of other transparent solid material

[1] A discourse delivered at the Royal Institution on Friday, March 24, by the Right Hon. Lord Rayleigh, F.R.S.

for glass, the choice is restricted by the presumed necessity of avoiding appreciable double refraction. Common salt is singly refracting, but attempts to use it were not successful. Opaque patches always interfered. With the idea that these might be due to included mother liquor, the salt was heated to incipient redness, but with little advantage. Transparent rock-salt artificially broken may, however, be used with good effect, but there is some difficulty in preventing the approximately rectangular fragments from arranging themselves too closely.

The principle of evanescent refraction may also be applied to the spectroscope. Some twenty years ago an instrument had been constructed upon this plan. Twelve 90° prisms of Chance's "dense flint" were cemented in a row upon a strip of glass (Fig. 1), and the whole was immersed in a liquid mixture of bisulphide of carbon with a little benzole. The dispersive power of the liquid exceeds that of the solid, and the difference amounts to about three-quarters of the dispersive power of Chance's "extra dense flint." The resolving power of the latter glass is measured by the number of centimetres of available thickness, if we take the power required to resolve the D-lines as unity. The compound spectroscope had an available thickness of 12 inches or 30 cm., so that its theoretical resolving power (in the yellow region of the spectrum) would be about 22. With the aid of a reflector the prism could be used twice over, and then the resolving power is doubled.

One of the objections to a spectroscope depending upon bisulphide of carbon is the sensitiveness to temperature. In the ordinary arrangement of prisms the refracting edges are vertical. If, as often happens, the upper part of a fluid prism is warmer than the lower, the definition is ruined, one degree (Centigrade) of temperature making nine times as great a difference of refraction as a passage from $D_1$ to $D_2$. The objection is to a great extent obviated by so mounting the compound prism that the refracting edges are *horizontal*, which of course entails a horizontal slit. The disturbance due to a stratified temperature is then largely compensated by a change of focus.

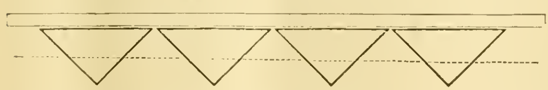

FIG. 1.

In the instrument above described the dispersive power is great—the D-lines are seen widely separated with the naked eye—but the aperture is inconveniently small (½-inch). In the new instrument exhibited, the prisms (supplied by Messrs. Watson) are larger, so that a line of ten prisms occupies 20 inches. Thus, while the resolving power is much greater, the dispersion is less than before.

In the course of the lecture the instrument was applied to show the duplicity of the reversed soda lines. The interval on the screen between the centres of the dark lines was about half an inch.

It is instructive to compare the action of the glass powder with that of the spectroscope. In the latter the disposition of the prisms is regular, and in passing from one edge of the beam to the other there is complete substitution of liquid for glass over the whole length. For one kind of light there is no relative retardation; and the resolving power depends upon the question of what change of wave-length is required in order that its relative retardation may be altered from zero to the quarter wave-length. All kinds of light for which the relative retardation is less than this remain mixed. In the case of the powder we have similar questions to consider. For one kind of light the medium is optically homogeneous, *i.e.* the retardation is the same along all rays. If we now suppose the quality of the light slightly varied, the retardation is no longer precisely the same along all rays; but if the variation from the mean falls short of the quarter wave-length it is without importance, and the medium still behaves practically as if it were homogeneous. The difference between the action of the powder and that of the regular prisms in the spectroscope depends upon this, that in the latter there is complete substitution of glass for liquid along the extreme rays, while in the former the paths of all the rays lie partly through glass and partly through liquid in nearly the same proportions. The difference of retardations along various rays is thus a question of a deviation from an average.

It is true that we may imagine a relative distribution of glass and liquid that would more nearly assimilate the two cases. If, for example, the glass consisted of equal spheres resting against one another in cubic order, some rays might pass entirely through glass and others entirely through liquid, and then the quarter wave-length of relative retardation would enter at the same total thickness in both cases. But such an arrangement would be highly unstable; and, if the spheres be packed in close order, the extreme relative retardation would be much less. The latter arrangement, for which exact results could readily be calculated, represents the glass powder more nearly than does the cubic order.

A simplified problem, in which the element of chance is retained, may be constructed by supposing the particles of glass replaced by thin parallel discs which are distributed entirely at random over a certain stratum. We may go further and imagine the discs limited to a particular plane. Each disc is supposed to exercise a minute retarding influence on the light which traverses it, and they are supposed to be so numerous that it is improbable that a ray can pass the plane without encountering a large number. A certain number ($m$) of encounters is more probable than any other, but if every ray encountered the same number of discs, the retardation would be uniform and lead to no disturbance.

It is a question of probabilities to determine the chance of a prescribed number of encounters, or of a prescribed deviation from the mean. In the notation of the integral calculus the chance of the deviation from $m$ lying between $\pm r$ is (see *Phil. Mag.*, 1899, vol. xlvii. p. 251)

$$\frac{2}{\sqrt{\pi}}\int_0^{\tau} e^{-\tau^2}\, d\tau,$$

where $\tau = r / \sqrt{(2m)}$. This is equal to ·84 when $\tau = 1·0$, or $r = \sqrt{(2m)}$; so that the chance is comparatively small of a deviation from $m$ exceeding $\pm \sqrt{(2m)}$.

To represent the glass powder occupying a stratum of 2 cm. thick, we may perhaps suppose that $m = 72$. There would thus be a moderate chance of a difference of retardations equal to, say, one-fifth of the extreme difference corresponding to a substitution of glass for liquid throughout the whole thickness. The range of wave-lengths in the light regularly transmitted by the powder would thus be about five times the range of wave-lengths still unseparated in a spectroscope of equal (2 cm.) thickness. Of course, no calculation of this kind can give more than a rough idea of the action of the powder, whose disposition, though partly a matter of chance, is also influenced by mechanical considerations; but it appears, at any rate, that the character of the light regularly transmitted by the powder is such as may reasonably be explained.

As regards the size of the grains of glass, it will be seen that as great or a greater degree of purity may be obtained in a given thickness from coarse grains as from fine ones, but the light not regularly transmitted is dispersed through smaller angles. Here again the comparison with the regularly disposed prisms of an actual spectroscope is useful.

At the close of the lecture the failure of transparency which arises from the presence of particles small compared to the wave-length of light was discussed. The tints of the setting sun were illustrated by passing the light from the electric lamp through a liquid in which a precipitate of sulphur was slowly forming (*op. cit.*, 1881, vol. xii. p. 96). The lecturer gave reasons for his opinion that the blue of the sky is not wholly, or even principally, due to particles of foreign matter. The molecules of air themselves are competent to disperse a light not greatly inferior in brightness to that which we receive from the sky.

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The honorary degree of M.A. was conferred in Convocation on Tuesday upon Mr. Roland Trimen, F.R.S.

Convocation has passed the decree accepting the offer of the Royal Geographical Society of 400*l.* for five years for the furtherance of geographical studies in Oxford, and providing an equal contribution from the funds of the University.

CAMBRIDGE.—The following is the speech delivered on May 11 by the Public Orator, Dr. Sandys, of St. John's

College, in presenting Prof. Kowalevsky, of St. Petersburg, for the honorary degree of Doctor in Science:—

Russorum ab imperio maximo legatus ad nos subito advectus est vir illustris, qui investigandi rationes novas inter primos secutus, animantium formas quasdam inferiores ex alia in aliam paullatim mutatas identidem indagavit; qui in confinio inter genera vertebris instructa et vertebris carentia iampridem moratus, Amphioxi speciem ambiguam primus explicavit; qui larvae denique Ascidianae cum vertebrato animalium genere affinitatem imprimis indicavit. Atqui, ne talium quidem virorum praeceptis attonitus, larvae illius degeneris propinquitatem reformidabit homo non terrestris tantum sed etiam caelestis originis conscius, qui angelis paullo minor, gloria et honore est coronatus, super oves et boves, super feras omnes, super volucres et pisces, super omnia quae maris per vias pererrant, a Deo constitutus.

Duco ad vos Zoologiae Professorem Petropolitanum, ALEXANDRUM KOWALEVSKY.

The General Board have issued a report recommending that the stipends of the Reader in Botany (Mr. F. Darwin), the Lecturer in Organic Chemistry (Mr. Ruhemann), the Lecturer in Experimental Psychology (Dr. Rivers), and the Curator in Zoology (Mr. D. Sharp), should be increased; and that new Lectureships in Palæozoology and in Physical Anthropology should be established.

A University Lectureship in Applied Mathematics will be vacant at Michaelmas by the resignation of Mr. Love, now Sedleian Professor at Oxford. Candidates are to send their names to the Vice-Chancellor by May 30. The stipend is 50*l.* a year.

The new Professorship of Agriculture, with a stipend of 800*l.* a year contributed by the Drapers' Company, was established by grace of the Senate on May 11.

---

THE Board of Education Bill was read for a third time, and passed, in the House of Lords on Monday.

THE foundation-stone of a new school and technical institute, connected with the Sir John Cass Foundation, in Jewry Street, Aldgate, was laid on Thursday last by the Bishop of London. The plans of Mr. A. W. Cooksey have been accepted for the new buildings, which will be in English Renaissance style, and will cost 45,000*l.*

MR. ANDREW CARNEGIE has written to the Right Hon. Joseph Chamberlain with reference to the proposed establishment of a University at Birmingham, and the correspondence is published in the *Birmingham Daily Post*. Mr. Carnegie refers in the correspondence to the great advantage which the iron and steel industries of the United States have derived from the Cornell University, and goes on to remark that "if Birmingham were to take that University as its model, where the scientific has won first place in the number of students, and give degrees in science as in classics, I should be delighted to contribute the last 50,000*l.* of the sum you have set out to raise to establish the scientific department." In addition to this Mr. Chamberlain, writing to the Lord Mayor of Birmingham, announces that an anonymous friend who had previously promised 25,000*l.* has agreed to increase his offer to 37,500*l.* on condition that the full amount of 250,000*l.* required for the *minimum* endowment is obtained. There still remains 12,000*l.* to be raised before the quarter of a million required is reached.

AT the annual celebration of Presentation Day of London University, held on May 10, the Earl of Kimberley presided for the first time as Chancellor. Referring to the Act passed last year, the Chancellor remarked that under the provisions of that Act and under the statutes made, the examination part of the University, by which the University had hitherto been known and in which it had done most excellent work, would be duly preserved. What was to be added was very important indeed, and it would become, he hoped, a great teaching University. They were at last beginning to appreciate the great changes which had taken place in the world, and in the advancement of science especially. Those changes had required others in the framing of the highest education. Not that they should for one moment abandon the old system of laying a good broad foundation of education, but that they should add to it the greater cultivation of the sciences, of economic science, and of all those arts which had grown to be of such great importance to this country. What they wanted was to bring together, as far as possible, all those various agencies provided for higher education in the metropolis.

INQUIRIES as to the schools in which leading men in various professions were educated have been made by *The School World*, and the results for men of science are published in the current number. Of 250 representative men of science—mostly Fellows of the Royal Society—chosen for the present inquiry, one-fifth received their early education either in private schools or at home under tutors. The schools which claim the greatest number of old pupils in the selected list are Edinburgh High School, Edinburgh Academy, and Aberdeen Grammar School. The Scotch schools are followed, as regards the number of old pupils of distinguished eminence in science, by the City of London School and King's College School. Eton, Harrow, and Rugby succeed these, and are in turn followed by Liverpool College, Royal Institution School (Liverpool), and St. Paul's. The remarkable point brought out by this comparison is the small part the great public schools have taken in training the leaders in science of the present day. When the men who are now in the foremost rank among philosophers were receiving their early education science was almost, if not quite, omitted from the public school curriculum, with the result that comparatively few boys from such schools have become eminent in the scientific world. The neglect of science in comparison with other subjects is shown by the fact that Eton, Harrow, Rugby, Winchester, Westminster, and one or two other public schools, though comparatively poor in their scientific record, are shown by *The School World* to have furnished the greatest number of leading men in Parliament, the Church, and the Law, Eton leading the way as regards numbers in each of these classes.

THE proposal to utilise the buildings of the Imperial Institute for the purposes of the new London University was referred to in the report read at the annual meeting of the Fellows of the Institute on Monday. Lord James of Hereford, who has succeeded the late Lord Herschell as chairman of the governing body, in moving the adoption of the report remarked that a new lease of life had been brought within the purview of the Institute. Those responsible for its management had been approached by the Government, who had to find accommodation for the London University. In the Institute they possessed a very great area of accommodation not needed by them, which could be devoted with very little adaptation for the purposes of the University. In the first place, to bring a great seat of learning under the roof of the Institute seemed to the governing body to be in accordance with the objects for which the Institute came into existence. But it was only right that he should tell them that in affording this accommodation to the London University they were receiving from the Government a very substantial return. He was not in the position to enter into any details, because all the arrangements had not yet been completed, but he might say that the negotiations were proceeding, and that by the financial return for the provision of the necessary accommodation for the University the governors of the Institute would be relieved of many burdens. The real result would be that they would have all anxiety removed with regard to the future conduct of the Institute.

## SCIENTIFIC SERIALS.

*Meteorologische Zeitschrift*, February.—Results of the international balloon ascent, by Dr. H. Hergesell. This is the first of a proposed series of papers; the present one deals principally with the range of temperature, as shown by observations made in a captive balloon at Strassburg on June 7 and 8, 1898. The results prove that in strata of free air, whose height exceeds a few hundred metres, the temperature possesses an extremely small diurnal range. During the night it scarcely amounts to a few tenths of a degree; while in the daytime a variation of some three or four degrees Centigrade may occur, even at a height of 800 metres, when vertical air currents exist. In the absence of these, the range would, in all probability, sink to a very low value.—On the characteristics of mild winters, by Dr. G. Hellmann. The last two mild winters have induced the author to revise his previous researches upon this subject, and he gives particulars of the 51 mild winters experienced in Berlin during the last 180 years. The principal results arrived at are: that mild winters scarcely ever occur singly, but in groups of two or three; that they are usually of long duration, from November to February or March; severe and long, late winters (February and March) seldom occur after mild mid-

winters; in mild mid-winters the greatest variations of temperature usually occur in January. After a very mild winter, a warm summer is more probable than after a winter which is only moderately mild. Dr. Hellmann pleads for synoptic charts for the whole globe—at least for short intervals, if longer periods cannot be undertaken.

In the *Journal of Botany* for April and May, Mr. A. Lister describes and figures some new or interesting species of Mycetozoa; Mr. E. A. N. Arber discusses the relationship to one another of the various forms of indefinite inflorescence; Mr. A. Gepp records the detection in Britain of a genus of Saprolegneous fungi, *Apodachlya;* Mr. G. S. West continues his account of the alga flora of Cambridgeshire; Mr. F. S. Williams, his critical notes on species of *Cerastium;* and Mr. H. C. Hart, his account of a botanical excursion in Donegal.

## SOCIETIES AND ACADEMIES.

### LONDON.

**Royal Society**, March 16.—"Experiments in Micro-metallurgy:—Effects of Strain. Preliminary Notice." By Prof. Ewing, F.R.S., and Walter Rosenhain, 1851 Exhibition Research Scholar, Melbourne University.

Much information has been obtained regarding the structure of metals by the methods of microscopic examination initiated by Sorby and successfully pursued by Andrews, Arnold, Charpy, Martens, Osmond, Roberts-Austen, Stead, and others. When a highly polished surface of metal is lightly etched and examined under the microscope, it reveals a structure which shows that the metal is made up in general of irregularly shaped grains with well-defined bounding surfaces. The exposed face of each grain has been found to consist of a multitude of crystal facets with a definite orientation. Seen under oblique illumination, these facets exhibit themselves by reflecting the light in a uniform manner over each single grain, but in very various manners over different grains, and, by changing the angle of incidence of the light, one or another grain is made to flash out comparatively brightly over its whole exposed surface, while others become dark.

The grains appear to be produced by crystallisation proceeding, more or less simultaneously, from as many centres or nuclei as there are grains, and the irregular more or less polygonal boundaries which are seen on a polished and etched surface result from the meeting of these crystal growths. The grains are, in fact, crystals, except that each of their bounding surfaces is casually determined by the meeting of one growth with another.

The experiments, of which this is a preliminary account, have been directed to examine the behaviour of the crystalline grains when the metal is subjected to strain.

For this purpose we have watched a polished surface under the microscope while the metal was gradually extended until it broke. By arranging a small straining machine on the stage of the microscope, we have been able to keep under continuous observation a particular group of crystalline grains while the piece was being stretched, and have obtained series of photographs showing the same group at various stages in the process. Strips of annealed sheet iron, sheet copper, and other metals have been examined in this way. We have also observed the effects of strain on the polished surfaces of bars in a 50-ton testing machine by means of a microscope hung from the bar itself, and have further observed the effects of compression and of torsion.

When a piece of iron or other metal exhibiting the usual granular structure is stretched beyond its elastic limit, a remarkable change occurs in the appearance of the polished and etched surface, as seen by the usual method of "vertical" illumination. A number of sharp black lines appear on the faces of the crystalline grains: at first they appear on a few grains only, and as the straining is continued they appear on more and more grains On each grain they are more or less straight and parallel, but their directions are different on different grains. At first, just as the yield-point of the material is passed, the few lines which can be seen are for the most part transverse to the direction of the pull. As the stretch becomes greater oblique systems of lines on other grains come into view.

The photograph, Fig. 1, taken from a strip of transformer plate (rolled from Swedish iron and annealed after rolling), gives a characteristic view of these lines as they appear after a moderate amount of permanent stretching, but long before the iron has reached its breaking limit.

The appearance of each grain is so like that of a crevassed glacier, that these dark lines might readily be taken for cracks.

The real character of the lines is apparent when the crystalline constitution of each grain is considered. They are not cracks, but *slips* along planes of cleavage or gliding planes.

Fig. 2 is intended to represent a section through the upper part of two contiguous surface grains, having cleavage or gliding planes as indicated by the cross-hatching, AB being a portion of the polished surface. When the metal is pulled beyond its elastic limit, in the direction of the line A B, yielding takes place

FIG. 1.—Soft sheet iron strained by tension. 400 diameters.

by finite amounts of slips occurring at a limited number of places in the manner shown at *a*, *b*, *c*, *d*, *e* (Fig. 3). This slip exposes short portions of inclined surfaces, and when viewed under normally incident light, these surfaces appear black because they return no light to the microscope. They are consequently seen as dark lines or narrow bands, extending over the polished surface in directions which depend on the intersection of the polished surface with the surfaces of slip.

We have proved the correctness of this view by examining these bands under oblique light. When the light is incident at

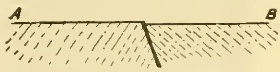

*Fig. 2. Before straining.*

only a small angle to the polished surface, the surface appears for the most part dark; but here and there a system of the parallel bands shines out brilliantly in consequence of the short cleavage or gliding surfaces which constitute the bands having the proper inclination for reflecting the light into the microscope. Rotation of the stage to which the strained specimen is fixed makes the bands on one or another of the grains flash out successively, with kaleidoscopic effect. In what follows we shall speak of these lines as slip-bands. Fig. 1, through a mixed illumination, shows some of the slip-bands bright and some dark.

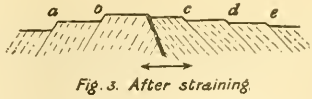

*Fig. 3. After straining.*

When the metal is much strained a second system of bands appears on some of the grains, crossing the first system at an angle, and in some cases showing little steps where the lines cross. These bands are clearly due to slips occurring in a second set of cleavage or gliding surfaces. Occasionally a third system of bands may be seen.

When the experiment is made with a polished but unetched specimen the slip-bands appear equally well. The boundaries of the grains are invisible before straining; but they can be distinguished as the strain proceeds, for the slip-bands form a cross-hatching which serves to mark out the surface of each grain.

Fig. 4 is another sample of iron strained by pull. The specimen in this case was a bar of Swedish iron, in which a comparatively large crystalline structure had been developed by annealing for some hours at 700° C. The photograph was taken after the bar had been broken in the testing machine, and shows with a magnification of 400 diameters a portion of the surface not far from the place of fracture.

The slip-bands are developed by compression as well as by extension. The bands developed by compression have apparently all the characteristics which they present in stretched pieces, and we could not, by microscopic examination of the surface, distinguish in this respect between the effects of compression and extension.

By twisting an iron bar well beyond the elastic limit the slip-bands are made to appear, for the most part, in directions parallel and perpendicular to the axis of twist.

A strip of sheet metal, such as iron or copper, in the soft state, when bent and unbent in the fingers, shows them well developed by the extension and compression of the surface.

These experiments throw what appears to us to be new light on the character of plastic strain in metals and other irregular crystalline aggregates. Plasticity is due to slip on the part of the crystals along cleavage or gliding surfaces. Each crystalline grain is deformed by numerous internal slips occurring at intervals throughout its mass. In general these slips no doubt occur in three planes, or possibly more, and the combination of the three allows the grain to accommodate itself to its envelope of neighbouring grains as the strain proceeds. The action is discontinuous: it is not a homogeneous shear but a series of finite slips, the portion of the crystal between one slip and the next behaving like a rigid solid. The process of slipping is one which takes time, and in this respect the aggregate effect is not easily distinguishable from the deformation of a viscous liquid.

We infer from the experiments that "flow" or non-elastic deformation in metals occurs through slip within each crystalline grain of portions of the crystal on one another along surfaces of cleavage or gliding surfaces. There is no need to suppose the portions which slip to be other than perfectly elastic. The slip,

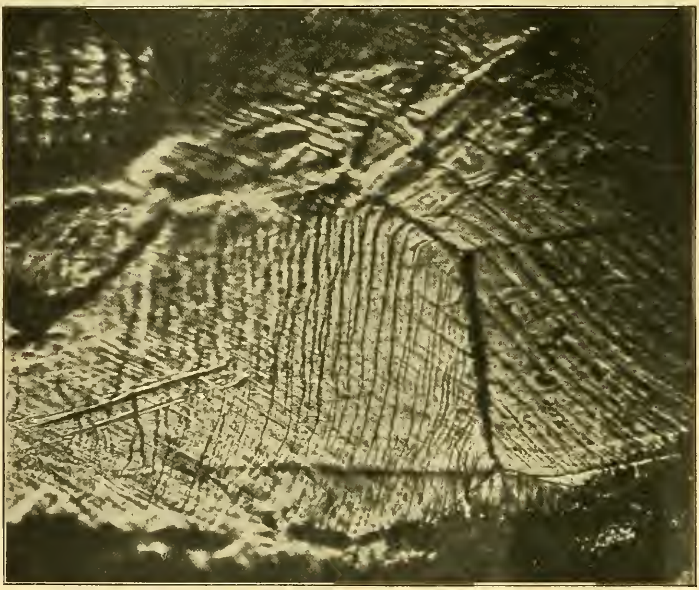

FIG. 4.—Swedish iron, much strained. 400 diameters.

when it occurs, involves the expenditure of work in an irreversible manner.

It is because the metal is an aggregate of irregular crystals that it is plastic as a whole, and is able to be deformed in any manner as a result of the slips occurring in individual crystals. Plasticity requires that each portion should be able to change its shape and its position. Each crystalline grain changes its shape through slips occurring within itself, and its position through slips occurring in other grains.[1]

The experiments were made in the engineering laboratory at Cambridge, and are being continued. The authors express their indebtedness to Sir W. Roberts-Austen and Mr. T. Andrews for advice as to the preparation of specimens of metals for microscopic examination.

We have developed the slip-bands in iron, steel, copper, silver, gold, nickel, bismuth, tin, gun-metal, and brass. In gold and silver they show particularly well, the crystalline structure being large and the lines straight. In copper also the lines are straighter and more regularly spaced than is general in iron. Most of these metals have been tested in the form of blocks under compression. A beautiful development of slip-bands may readily be produced by pinching a button of polished silver or copper in a vice, or by bending a strip of sheet metal.

In carbon steels we have found the slip-bands considerably more difficult to observe than in wrought iron. The smaller granular structure of steel apparently makes the slip-bands correspondingly minute. In mild steel they are seen readily enough, but in a rather high carbon steel we succeeded in seeing them only with difficulty in the "ferrite" areas under a magnification of 1000 diameters. A cast piece of the nearly pure iron used for dynamo magnets showed a relatively very large granular structure and well marked slip-bands.

[1] Attention should be called in this connection to the experiments of Messrs. McConnel and Kidd on the plasticity of glacier ice (*Roy. Soc. Proc.*, vol. xliv. p. 331). They found that bars cut from glacier ice which is an aggregate of irregular crystals are plastic.

April 27.—"On the Luminosity of the Rare Earths when heated in vacuo by means of Kathode Rays." By A. A. Campbell Swinton. Communicated to the Royal Society by Lord Kelvin, F.R.S.

For incandescent gas mantles it is found that certain definite mixtures of the rare earths are necessary in order to obtain the maximum luminosity. For instance, a mantle consisting of pure thoria or pure ceria will in the Bunsen flame only give about one-eleventh of the light of one composed of 99 per cent of thoria and 1 per cent of ceria, which is the mixture used by the Welsbach Company.

In order to explain this remarkable fact, several contradictory theories have been propounded, and with a view to elucidating matters the author has made experiments in which mantles composed of different pure oxides and mixtures were heated by kathode ray bombardment in vacuo.

The mantles were prepared according to the ordinary Welsbach process, and in order to obtain accurate comparisons the mantles were made in patchwork, each complete mantle being made up of two or four sections separately impregnated with different solutions. The mantles were so mounted in the vacuum tube that the kathode rays impinged equally upon the portions that consisted of different oxides and mixtures, so that an equal amount of energy was imparted to each sample. Under these conditions the Welsbach mixture of thoria plus 1 per cent. of ceria was found to give very little more light than pure thoria, the difference probably not exceeding 5 per cent., but on starting the kathode discharge the mixture heated up to incandescence more rapidly, and on stopping the discharge cooled more rapidly than the pure thoria. At the same time it was found that with an intensity of kathode rays that gave a brilliant light both with pure thoria and with the Welsbach mixture, a mixture of 50 per cent. thoria and 50 per cent. ceria, and also a piece of mantle composed of pure ceria, gave practically no light, becoming barely red-hot.

The maximum luminosities could only be obtained at a critical and highly unstable degree of vacuum, which rendered accurate photometrical measurements impossible, but with pure thoria the amount of light under favourable conditions was estimated at at least 150 candle-power per square inch of incandescent surface, this being obtained with an expenditure of electric energy at about 8000 volts pressure of approximately one Watt per candle.

The kathode rays were found to have a reducing action on the oxides, which became discoloured under the bombardment, the discoloration disappearing owing to re-oxidation on the admission of a small quantity of air. Air so admitted while the tube was working was rapidly absorbed, and after the process of admitting air and absorbing it had been repeated several times, the degree of exhaustion which gave the maximum incandescence was found to have altered considerably, the residual gas having apparently become less conducting.

In place of air, oxygen and hydrogen were separately used as the residual gas, but without any difference in the luminosity.

These experiments show that thoria and ceria, both alone and mixed, behave quite differently when heated by kathode ray bombardment than when heated in a Bunsen flame. In the latter thoria plus 1 per cent. of ceria gives many times as much light as pure thoria alone, while when incandesced by kathode rays of equal intensity the difference, though in a similar direction, is only just appreciable. Again, in the flame, pure ceria gives just about the same amount of light as pure thoria, while with a given intensity of kathode ray bombardment thoria gives a brilliant light, while ceria gives practically none. In arriving at any satisfactory theory of the luminescent properties of the rare earths, these results will have to be taken into account.

"A Quartz Thread Gravity Balance." By R. Threlfall and J. A. Pollock.

The balance is of the horizontal, stretched, quartz thread type. One end of the thread is attached by soldering to a spring of peculiar construction; the other end is attached to the axle of the vernier arm of a sextant. At the centre of the thread a bit of brass wire is attached by soldering, so that the thread crosses the wire, which is about two cm. long, at right angles. The centre of gravity of the bit of wire, which will be referred to as the "lever," lies a little to one side of the thread, so that when the thread is untwisted the lever hangs vertically. The thread is stretched so that, in spite of the weight of the lever, it hangs almost horizontally. To make this arrangement into a gravity balance, it is only necessary to turn the lever round the thread as axis, so that each half of the latter receives about three turns ($3 \times 360$ degrees) of twist. The lever is adjusted till, under these circumstances, it hangs nearly horizontally. A discussion of the theory of the balance shows that if the twist be now reduced the centre of gravity of the lever will rise and the position of the lever become unstable soon after its centre of gravity rises above the horizontal plane through the thread. The nearly horizontal position of the lever is secured during observation by means of a microscope, which can be focussed upon the end of the lever, and which is rigidly attached to the framework of the instrument. Gravitational attraction on the lever is thus balanced by the torsional rigidity of the quartz fibre, and the observations consist in noting the increase or diminution of twist, as applied at one end of the thread, necessary to bring the lever to its sighted position. The whole apparatus is enclosed in a tube which is air-tight, the vernier axle working through a sort of mercury stuffing-box. Exact thermometry is required, and is supplied by means of a platinum thermometer lying alongside the thread.

The instrument only gives relative values of gravity, referring an excess, or defect, of gravitational force to the difference of gravitational intensity at two stations selected as having known constants, in the present case Sydney and Melbourne.

The difficulties which have been met with during many years' work arise from the warping of the metallic parts of the instrument under changes of temperature and in the imperfect elastic properties of fused quartz threads.

The possible errors of a single observation are shown, from a discussion of the detail of the instrument, to amount to about one part in 300,000 of the value of $g$ at any point, and by a discussion of three journeys between Sydney and Hornsby (N.S.W.), it is shown that the consistency actually realised is about one in 500,000 of $g$.

Many journeys have been made with the instrument in New South Wales, Victoria, and Tasmania, from which the perfect portability of the instrument has been ascertained, as well as its convenience in practice. A single observation takes only a few minutes after the temperature has arrived at a maximum or minimum, but the packing and unpacking occupy more than an hour—in general about three hours are required. The weight of the total outfit, with ordinary appliances just as they came to hand in the laboratory, is 226 pounds, but this might be halved by making the appliances specially. The paper contains the complete theory of the instrument, working drawings exhibiting its construction, and an account of experiments made with various modifications of the instrument.

"On the Electrical Conductivity of Flames containing Salt Vapours." By Harold A. Wilson, B.Sc. (Lond. and Vic.), 1851 Exhibition Scholar. Communicated by Prof. J. J. Thomson, F.R.S.

The experiments described in this paper were undertaken with the object of following up the analogy between the conductivity of salt vapours and that of Röntgenised gases, and especially of getting some information about the velocities of the ions in the flame itself.

They are to some extent a continuation of the research of which an abstract has already been published in the *Proceedings* of the Royal Society ("The Electrical Conductivity and Luminosity of Flames containing Vaporised Salts," by A. Smithells, H. M. Dawson, and H. A. Wilson, *Roy. Soc. Proc.*, vol. lxiv. p. 142).

The paper is divided into the following sections:—

(1) Description of the apparatus for producing the flame.

(2) The relation between the current and E.M.F. in the flame.

(3) The fall of potential between the electrodes.

(4) The ionisation of the salt vapour.

(5) The relative velocities of the ions in the flame.

(6) The relative velocities of the ions in hot air.

(7) Conclusion.

The current with a large E.M.F. was found to be independent of the distance between the electrodes in the flame, provided both were hot enough to glow; it was much greater when the hotter electrode was negative than when it was positive. When both electrodes were hot, the fall of potential between them was found to be very like that observed in the discharge through gases at low pressure. If one of the electrodes was cool, then nearly all the fall of potential occurred very near to it. Practically all the ionisation of the salt vapours appeared to take place at

the surfaces of the glowing electrodes. The velocities of the ions in the flame were estimated by finding the electric intensity required to cause them to move down the flame against the upward stream of gases. The positive ions of all the alkali metal salts had a velocity of about 60 $\frac{\text{cms.}}{\text{sec.}}$ for one volt per cm. The corresponding velocity of the negative ions was about 1000 $\frac{\text{cms.}}{\text{sec.}}$ In a current of hot air the corresponding velocities were as follows:—

(1) Negative ions of salts of Li, Na, K, Rb, Cs, Ca, Sr, and Ba, 26·0 $\frac{\text{cms.}}{\text{sec.}}$

(2) Positive ions of salts of Li, Na, K, Rb, and Cs, 7·2 $\frac{\text{cms.}}{\text{sec.}}$

(3) Positive ions of salts of Ca, Sr, and Ba, 3·8 $\frac{\text{cms.}}{\text{sec.}}$

The greater velocity of the negative ions enables the phenomena of unipolar conduction &c., to be easily explained.

**Physical Society**, May 12.—Prof. Perry, Vice-President, in the chair.—Dr. Lehfeldt read a note on the vapour pressure of solutions of volatile substances. The change in vapour pressure of a solvent due to the solution in it of a small quantity of volatile material has been calculated on the basis of Raoult's rule for the corresponding case of a non-volatile dissolved body. The author has interpreted the formula of Nernst in the following words:—When a small quantity of volatile substance is dissolved in a liquid the vapour pressure of the liquid is altered in the ratio of the molecular fractional amount of solvent in the liquid to that in the vapour. In order to test this formula, it has been applied to the results of experiments made on four series of liquids, viz. alcohol with benzene and toluene, and carbon tetrachloride with benzene and toluene. In the case of normal solutions, such as carbon tetrachloride in toluene, carbon tetrachloride in benzene, and benzene in carbon tetrachloride, the agreement between the observed and calculated values of the percentage composition of the liquid was remarkably good. In the case of toluene in carbon tetrachloride the solution contained about 29 per cent. of the dissolved body; and as the range of applicability of the formula had probably been exceeded, the agreement was not so good as in the previous examples. The mixtures containing alcohol show maxima of vapour pressure, and on this account the departure from the formula is so much more marked that it is impossible to apply it except in the case of very dilute solutions. The temperature used throughout the experiments was 50° C.—The Secretary read a note by Prof. W. B. Morton and Dr. Barton on the discussion of their paper, on the criterion for an oscillatory discharge of a condenser. In the discussion which followed the reading of the paper, it was pointed out that the result obtained, viz. that on taking into account the distribution of the current in the wire—a condenser having the critical capacity on the simple theory gives an oscillatory discharge—seems to be contradicted by the well-known fact that the resistance of the wire is greater and the inductance less for oscillatory than for steady currents. The explanation of the apparent paradox is to be found in the effect of the damping on the inductance. When the damping is great and the frequency small, as in the neighbourhood of the critical case, what may be termed the equivalent inductance becomes greater than the steady current value. It is shown that this increase in "L" outweighs the increase of "R" in its effect upon the criterion for oscillatory discharge. An examination of the expression for the equivalent inductance in the case of iron shows that it is greater than the steady current value if the ratio of one amplitude to the next is greater than $e^{n/200}$ where $n$ is the frequency of the oscillation. Since the decrease of "L" with maintained oscillations is due to a surface concentration of current, it is suggested that there must be an axial concentration in the case of damped vibrations. Following the method of Maxwell for determining the current density at a distance from the axis of a wire, an expression for the current was introduced containing a damping coefficient. The "quasi-amplitude" of the disturbance at any point in the wire was thus obtained. An examination of the result shows that making the damping zero indicates a surface concentration. If, on the other hand, the damping is great, the expression for the amplitude increases as the distance from the axis decreases, and we get an axial concentration. Assuming sufficient damping to produce this effect, it is shown that as we go through the point $r = \frac{a}{\sqrt{2}}$, where $a$ is the radius of the wire, we pass from a greater value of current density in the inner parts to a less in the outer than would correspond to a uniform distribution throughout the wire. From general reasoning the authors think that if a rapidly damped disturbance is propagated into a wire from its boundary, and if the oscillations are slow enough to allow the current to penetrate to the core, we should expect to find an axial concentration in the latter stages of the phenomenon. Dr. Lehfeldt said that Prof. Lodge had pointed out, at the reading of the paper, that the solution the authors obtained changed character at the critical resistance. As this point had not been considered in the note, he supposed that the change in character made no difference to the results obtained. The Chairman expressed his interest in the proof of the existence of an axial concentration.—Mr. Addenbrooke exhibited and described a quadrant electrometer for application to alternating current measurements. The author has substituted for cylindrical quadrants two sets of flat plates, the top set being adjustable. In this way the range of the instrument is considerably increased. The ability to remove one or more of the top quadrants makes the needle very accessible. By lowering the needle on to the bottom quadrants, and then bringing down one of the top plates, the instrument can be carried with safety. One of the top quadrants can be worked up and down by a worm gear, and by this motion the "electrical zero" of the electrometer is obtained. The suspension consists of a flat phosphor bronze strip, the torsion of which is found to be perfectly uniform, there being no fatigue effect. The case of the instrument contains windows, so that the needle can be viewed from two directions at right angles, and there are screw motions to centre the needle with respect to the quadrants. To reduce the effect of air convection currents upon the needle, the inside of the case is lined with cotton velvet. The quadrants are supported on brass bars passing through long ebonite sleeves in the bottom of the instrument. This gives good insulation without the use of sulphuric acid, and there is no Leyden jar or condenser in connection with the needle. When using the electrometer idiostatically with the finest strip, a light needle, and the quadrants one-tenth of an inch apart, a difference of potential of one volt will produce a deflection of about 5 mms. upon a screen two metres distant. Using the instrument heterostatically with 100 volts on the needle one-fifth of an inch between the quadrants and half a volt acting across them a deflection of 200 mms. can be obtained. This sensitiveness is about twelve times as great as that got from instruments designed by Kelvin, Mascart, and Haga. Mr. Addenbrooke then showed how, in conjunction with a voltmeter and an ammeter, it was possible with his instrument to determine all the factors of an alternating current system. The increased sensitiveness of the electrometer renders it possible to measure currents of any magnitude with a very small waste of energy. Mr. Gaster pointed out that the measurement of self-induction with an electrometer could only be carried out practically if the current curve was a sine curve. He said that in curves obtained from a Ganz motor a correction amounting to 7 per cent. had to be applied. The Chairman said that even if the curve obtained was a sine curve, the electrometer was never used in this country for measuring self-induction. Prof. Herschel asked if it were possible to adjust the quadrants after the needle had been charged Mr. Addenbrooke then purposely disturbed the position of the adjustable plate, and, after charging the needle, reduced the deflection to zero by the worm gear. The author said that for high voltages the curve of calibration was different to that obtained from the ordinary formula. The Chairman said that this discrepancy was probably due to want of perfect symmetry. In a paper read before the Royal Society by Perry, Ayrton and Mather, it was shown that the presence of the guard around the mirror of an ordinary electrometer was sufficient to affect the needle when working with high voltages. In working with the plates very close together he was afraid the symmetry would be liable to be disturbed by a slight tilting of the needle due to electrostatic attraction. The author observed that the plates were only very close together when working with low voltages.

**Chemical Society**, May 4.—Prof. Thorpe, President, in the chair.—The following papers were read:—On the combustion of carbon disulphide, by H. B. Dixon and E. J. Russell. Carbon disulphide undergoes a phosphorescent combustion in air at temperatures below its ignition point, the lowest observed

value for which was 232°; prolonged heating of carbon disulphide at 230°, or prolonged exposure to bright light, causes slight decomposition. The decomposition of carbon bisulphide vapour by detonation is not propagated as an explosion, and no explosive wave could be propagated in mixtures of the vapour and oxygen containing less than 40 per cent. of the latter.—The action of nitric oxide on nitrogen peroxide, by H. B. Dixon and J. D. Peterkin. A very slight increase of volume occurs on mixing nitric oxide with nitrogen peroxide at 27°, but a considerable expansion attends the mixing of inert gases like nitrogen with the peroxide, owing to dissociation of the latter; these results may be explained by the equation

$$N_2O_3 \rightleftarrows NO + NO_2$$

on the supposition that at 27° the dissociation is nearly complete.—On the mode of burning of carbon, by H. B. Dixon. It is shown that Lang's view that carbon dioxide is the first product of the combustion of carbon, and that carbon monoxide is only produced by the subsequent reduction of the dioxide, is invalid.—Crystalline glycollic aldehyde, by H. J. H. Fenton and H. Jackson. The aqueous syrup containing glycollic aldehyde obtained by heating dihydroxymaleic acid with water, yields a hexose, $C_6H_{12}O_6$, on evaporation; during the latter process a small proportion of crystalline glycollic aldehyde sublimes; when first dissolved in water the aldehyde has the composition $C_4H_8O_4$, but after about twenty-four hours the molecular composition becomes $C_2H_4O_2$.—On the blue salt of Fehling's solution and other cuprotartrates, by O. Masson and B. D. Steele. The blue salt of Fehling's solution when dried *in vacuo* has the composition $K_3C_{12}H_9Cu_4O_{19}$, $4H_2O$, and contains a complex negative radicle of which copper is a part; none of the copper is electropositive.—The preparation of acid phenolic salts of dibasic acids, by S. B. Schryver.—The maximum pressure of naphthalene vapour, by R. W. Allen. The author has prepared, from new experimental data, tables showing the vapour pressure of naphthalene and giving the weight of naphthalene required to saturate a cubic metre of gas at temperatures ranging from 0° to 130°.—Scoparin, by A. G. Perkin. Scoparin, the colouring matter of broom, s probably a methoxyvitexin.—On a new compound of arsenic and tellurium, by E. C. Szarvasy and C. Messinger. The compounds of arsenic with elements of the oxygen-sulphur series which are most stable at high temperatures are $As_2O_3$, $As_2S_2$, $As_2Se$; since the differences between the molecular weights in this series of compounds are 15 and 16, it was thought probable that the compound $As_2Te_3$ should be formed at high temperatures. The authors have obtained this compound.—The action of hydrogen peroxide on secondary and tertiary aliphatic amines. Formation of alkylated hydroxylamines and oxamines, by W. R. Dunstan and E. Goulding.—The enantiomorphously related tetrahydroquinaldines, by W. J. Pope and S. J. Peachey. The authors have separated synthetic tetrahydroquinaldine into a dextro- and a lævo-rotatory isomeride by crystallising its salts with camphorsulphonic acids.

**Entomological Society**, May 3.—Mr. R. McLachlan, F.R.S., in the chair.—Dr. A. L. Bennett exhibited various insects which he had collected in the French Congo. They included a species of Mantidæ remarkable for its very striking resemblance in coloration to a piece of bark.—Mr. F. Enock exhibited a living specimen of *Nepa cinerea* infested with a number of minute red *Acari* on the ventral surface of the abdomen. He also showed eggs of *Nepa* and *Notonecta* lying *in situ* in decayed leaf-stalks of *Alisma*, and described the mode of oviposition as observed by himself in both of these genera. He then exhibited a living example of the remarkable aquatic Hymenopteron—*Prestwichia aquatica*, Lubb., and said it was one of a brood of nine, including eight ♀♀ and one ♂, that issued on May 1 from a single egg of *Colymbetes* found on September 5, 1898.—Mr. Merrifield showed some specimens of *Hemaris bombyliformis*, Esp., with the scales still covering the central portions of the wings. He said these scales, which are present immediately after the emergence of the insect but soon become detached, may be rendered adherent by allowing a very weak solution of indiarubber in benzoline to run over the wings.—Mr. C. H. Dolby-Tyler communicated a paper on the development of *Ceroplastes roseatus*, Towns. and Cockl.

**Mathematical Society**, May 11.—Prof. H. Lamb, F.R.S., Vice-President, in the chair.—Major MacMahon, R.A., F.R.S., communicated some results he has obtained in the theory of partitions.—Mr. H. M. Macdonald read a paper on the zeroes of aspherical harmonic, $P_n^m(\mu)$, considered as a function of $n$.—Mr. W. F. Sheppard gave an account of his paper on the statistical rejection of extreme variations, single or correlated (normal variation and normal correlation).

MANCHESTER.

**Literary and Philosophical Society**, April 25.—Mr. J. Cosmo Melvill, President, in the chair.—At this the annual general meeting, Mr. R. H. Inglis Palgrave, F.R.S., and Prof. William Ramsay, F.R.S., were elected honorary members of the Society.—The annual report (as amended) and the statement of accounts were adopted, and the following were elected officers and members of the Council for the ensuing year:—President, Prof. Horace Lamb, F.R.S.; vice-presidents, Prof. Osborne Reynolds, F.R.S., Mr. Charles Bailey, Mr. J. Cosmo Melvill, and Prof. W. Boyd Dawkins, F.R.S.; secretaries, Mr. R. F. Gwyther and Mr. Francis Jones; treasurer, Mr. J. J. Ashworth; librarian, Mr. W. E. Hoyle; other members of the Council, Prof. H. B. Dixon, F.R.S., Mr. Francis Nicholson, Mr. J. E. King, Mr. R. L. Taylor, Mr. F. J. Faraday, and Mr. W. H. Johnson.—At the ordinary meeting held afterwards, Prof. Dixon described an apparatus for bringing together nitrogen peroxide and nitric oxide in order to determine whether any combination occurs between the gases.

PARIS.

**Academy of Sciences**, May 8.—M. van Tieghem in the chair.—On the absolute measurement of time, deduced from the laws of universal attraction, by M. G. Lippmann. The unit of time suggested is based upon the proposition that the numerical value of the Newtonian constant is independent of the units of length and mass, and depends uniquely upon the choice of the unit of time. Inversely, the magnitude of the interval of time taken as unity is determined without ambiguity when the numerical value of the Newtonian constant which corresponds to it is given.—Anatomical and physiological characters of plants rendered artificially Alpine by alternation between extreme temperatures, by M. Gaston Bonnier. Alpine temperature conditions were imitated by keeping the plants in an ice box during the night, and exposing fully to the sun during the day. The petioles of the leaves develop more rapidly under these conditions, and the leaves, which are smaller and thicker, have a more highly developed layer of pallisade tissue, and frequently the reddish coloration of Alpine plants. The flowers are relatively larger and more highly coloured than those grown under ordinary conditions.—M. Prillieux was elected a member of the Botanical section, in place of the late M. Naudin.—On the circumstances which modify the images reflected by a mercury bath, and on the transmission through the soil of vibrations produced at the surface, by M. G. Bigourdan. In the hope of securing a steadier mercury surface, the bath was placed at varying distances from the surface of the earth. It was then found that two quite distinct classes of earth tremors could be distinguished, the one slow and regular, to which the name undulation is given, the other rapid and irregular vibrations.—On the pencils which correspond to the case where the series of Laplace is limited in one direction, by M. C. Guichard.—The groups of the order $p^2q^2$, $p$ being a number greater than $q$, by M. Le Vavasseur.—On the electric capacity of badly conducting bodies, by MM. I. I. Borgmann and A. A. Petrovsky.—On an intense source of monochromatic light, by MM. Ch. Fabry and A. Perot. The new source suggested is the electric arc between two surfaces of mercury *in vacuo*. The mercury is contained in two concentric glass tubes, the inner one only just separating the two mercury surfaces. On giving the tube a slight shock a momentary connection is set up, and the arc starts. For a perfectly stable arc a potential of about thirty volts is necessary, and a current of from two to three amperes. The light is not perfectly monochromatic, but may be easily rendered so by the interposition of cells containing suitable absorption media. Thus, a mixture of didymium chloride and potassium bichromate cuts off all rays except the green ray, the most useful ray for general purposes.—On the ratio of the atomic weights of hydrogen and oxygen, by M. A. Leduc. By taking into account the increase of pressure observed to take place when hydrogen and oxygen gases are mixed, the number for the ratios of the atomic weights deduced from the density of detonating

gas (15·898), is increased to 15·878, a number sensibly in agreement with the 15·88 found by the author by the gravimetric method.—On the increase of pressure produced by the mixture of two gases, and on the compressibility of the mixture, by M. Daniel Berthelot. The formulæ proposed by the author in a previous paper are applied to the gas mixtures, $SO_2+CO_2$, $N_2+O_2$, and $H_2+O_2$, and the results compared with the experiments of Sacerdote, Leduc, Rayleigh, and the author. The agreement is very close.—Researches on the separation of traces of bromine existing in chlorides, by M. H. Baubigny. A strong solution of the chloride, to which a large amount of copper sulphate has been added, is treated with potassium permanganate in the cold, and the whole reduced to dryness *in vacuo*. The whole of the bromine is thus given off, together with a little chlorine; the original method proposed by the author and M. Rivals is then applied to this mixture. Two test analyses show satisfactory results, even when only ·005 gram of bromide was present with 12 grams of chloride.—On the impurities of aluminium, by M. Adolphe Minet.—On magnesium phosphide, by M. Henri Gautier. The phosphide $Mg_3P_2$ was prepared in a pure state by the direct combination of the elements in a stream of hydrogen. Pure $PH_3$ is obtained on treating this with water.—On the flame of hydrogen, by MM. Schlagdenhauffen and Pagel. The violet-blue colour of a hydrogen flame obtained when the gas is prepared from zinc is not due to sulphur, as proposed by Salet, but selenium. Some selenium is invariably left behind in the residue, probably as lead selenide.—Hydrogenation of acetylene in presence of nickel, by MM. Paul Sabatier and J. B. Senderens. A mixture of hydrogen and acetylene acts vigorously upon reduced nickel, even in the cold, ethylene, ethane, and liquid hydrocarbons being produced in quantity.—On the dextrines arising from saccharification, by M. P. Petit.—Method for rapidly measuring the dimensions of small objects, independently of their distance. Application to pupillometry and to laryngometry. Illusion due to the muscular sense in the appreciation of the size of objects, by M. Th. Guilloz.—Pathological physiology of pregnancy, by MM. Charrin and Guillemonat.—The influence of freezing upon the development of the hen's egg, by M. Étienne Rabaud. The eggs were not killed by exposure to $-15°$ C., but the development was markedly affected, and that permanently.—Some remarks on the *Haementeria costata* of Müller, by M. A. Kowalevsky.—On the existence of a fauna of Arctic animals in the Charente at the Quaternary epoch, by MM. Marcellin Boule and Gustave Chauvet.—New researches on the caverns of Padirac, by MM. Armand Viré and Étienne Giraud.—On the ascent of the *Balaschoff* on March 24, by M. G. Le Cadet.

## DIARY OF SOCIETIES.

*THURSDAY*, MAY 18.

ROYAL SOCIETY, at 4.30.—Bakerian Lecture: The Crystalline Structure of Metals: Prof. J. A. Ewing, F.R.S., and W. Rosenhain.—The Yellow Colouring Matters accompanying Chlorophyll and their Spectroscopic Relations: C. A. Schunck.—The Diffusion of Ions into Gases: J. S. Townsend.—The Diurnal Range of Rain at the Seven Observatories in connection with the Meteorological Office, 1871–1890: Dr. R. H. Scott, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Electric Locomotives in Practice and Tractive Resistance in Tunnels, with Notes on Electric Locomotive Design: P. V. McMahon.

CHEMICAL SOCIETY, at 8.—Corydaline, Part VI.: Dr. J. J. Dobbie and A. Lauder.—Oxidation of Furfural by Hydrogen Peroxide: C. F. Cross, E. J. Bevan, and T. Freiberg.

*FRIDAY*, MAY 19.

ROYAL INSTITUTION, at 9.—Runic and Ogam Characters and Inscriptions in the British Isles: The Lord Bishop of Bristol.

EPIDEMIOLOGICAL SOCIETY, at 8.30.—A Study of Enteric Fever in the Netherlands: Prof R. H. Saltet.

*TUESDAY*, MAY 23.

ROYAL INSTITUTION, at 3.—Recent Advances in Geology: Prof. W. J. Sollas, F.R.S.

ROYAL PHOTOGRAPHIC SOCIETY, at 8.—Corea: Mrs. Isabella Bishop.

*WEDNESDAY*, MAY 24.

GEOLOGICAL SOCIETY, at 8.—On the Distal End of a Mammalian Humerus from Tonbridge: Prof. H. G. Seeley, F.R.S.—On Evidence of a Bird from the Wealden Beds of Ansty Lane, near Cuckfield: Prof. H. G. Seeley, F.R.S.—On the Rhyolites of the Hauraki Goldfields (New Zealand): J. Park and F. Rutley.—On the Progressive Metamorphism of some "Dalradian" Sediments in the Region of Loch Awe: J. B. Hill.

*THURSDAY*, MAY 25.

ROYAL INSTITUTION, at 3.—Water Weeds: Prof. L. C. Miall F.R.S.

*FRIDAY*, MAY 26.

ROYAL INSTITUTION, at 9.—Climbs and Explorations in the Andes: Sir W. Martin Conway.

PHYSICAL SOCIETY, at 5.—On the Thermal Properties of Normal Pentane, Part 2: Prof. S. Young and Mr. Rose-Innes.—On the Distribution of Magnetic Induction in a Long Iron Bar: C. G. Lamb.

## BOOKS, PAMPHLETS, and SERIALS RECEIVED.

BOOKS.—Cours Elémentaire de Zoologie: R. Perrier (Paris, Masson).—Chapters on the Natural History of the U.S.: Dr. R. W. Schufeldt (Gay).—Das Tierreich, 7 Liefg.: Profs. Canestrini and Kramer (Berlin, Friedländer).—Ditto, 8 Liefg.: Prof. K. Kraepelin (Berlin, Friedländer).—Electromagnetic Theory: O. Heaviside, Vol. 2 (*Electrician* Company).—The Tides Simply Explained: Rev. J. H. S. Moxly (Rivingtons).—A Manual of Surgical Treatment: Prof. W. W. Cheyne and Dr. F. F. Burghard, Part 1 (Longmans).—Physique et Chimie Viticoles: A. de Saporta (Paris, Carré and Naud).—The Aborigines of Tasmania: H. Ling Roth, 2nd edition (Halifax, King).

PAMPHLETS.—Die Elemente des Erdmagnetismus, &c.: Dr. H. Fritsche (St. Petersburg).—Man the Microcosm: L. Hall, Part 1 (Williams).—Die Lokalisation Morphogenetischer Vorgänge: H. Driesch (Leipzig, Engelmann).—Die Aufstellung der Tiere in Neuen Museum zu Darmstadt: G. von Koch (Leipzig, Engelmann).—Siebenter Jahres-Bericht des Sonnblick-Vereines für das Jahr 1898 (Wien).

SERIALS.—Science Gossip, May (Strand).—Botanische Jahrbücher, Siebr. Bd. 1 and 2 Heft (Leipzig).—Fortnightly Review, May (Chapman).—Zeitschrift für Physikalische Chemie, xxviii. Band, 4 Heft (Leipzig).—Himmel und Erde, April (Berlin).—Natural Science, May (Pentland).—Journal of Botany, May (West).—Observatory, May (Taylor).—Journal of the Chemical Society, May (Gurney).—Geographical Journal, May (Stanford).—Monthly Weather Review, January (Washington).—Proceedings of the Royal Society of Edinburgh, Vol. xxii. pp. 361–440 (Edinburgh).—Engineering Magazine, May (Strand).—Physical Review, March (Macmillan).—Scientia, No. 3 (Paris, Carré).—Journal of Applied Microscopy, March (Rochester, N.Y.).—L'Anthropologie, Tome x. ## RECENT WORKS ON MEDICAL SCIENCE.

1. *The Administrative Control of Tuberculosis.* Being the Harben Lectures delivered in 1898, before the Royal Institute of Public Health, by Sir Richard Thorne Thorne, K.C.B., F.R.S. Pp. 73. (London: Baillière, Tindall, and Cox, 1899.)
2. *Die Bedeutung der Reize für Pathologie und Therapie im Lichte der Neuronlehre.* Von Dr. A. Goldscheider. Pp. 88. (Leipzig: Barth, 1898.)
3. *Twenty-seventh Annual Report of the Local Government Board*, 1897-98. Supplement containing the Report of the Medical Officer for 1897-98. Pp. 331. (London: Her Majesty's Stationery Office, 1898.)
4. *The Natural History of Digestion.* By A. Lockhart Gillespie, M.D., F.R.C.P., F.R.S. (Ed.) Pp. 427. "Contemporary Science Series." (London: Walter Scott, Ltd., 1898.)
5. *Diet and Food considered in Relation to Strength and Power of Endurance, Training and Athletics.* By Alexander Haig, M.A. and M.D. (Oxon.), F.R.C.P. Five Illustrations. Pp. 86. (London: J. and A. Churchill, 1898.)
6. *On Centenarians and the Duration of the Human Race.* By T. E. Young, B.A., F.R.A.S. Pp. 145. (London: Charles and Edwin Layton, 1899.)

1. THE subject-matter of the Harben Lectures, of which the book before us consists, is at the present time of special interest, not only to the medical profession, but to the general public. The country is now thoroughly roused to the importance of the control of tuberculosis, and although the measures considered in Sir R. Thorne Thorne's book are intended primarily for sanitary officials, they should prove of extreme interest and importance to both the general practitioner and the agriculturist.

In the first lecture, the author emphasises the fact that while of recent years the death-rate from pulmonary consumption has very greatly diminished, no corresponding diminution has been observed in the number of deaths due to tubercular lesions of the alimentary tract. The difference ætiologically between these two classes of cases consists mainly in the air being the source of infection in the former, and the food in the latter. The enormous improvement in the arrangement of dwelling-houses and streets with regard to ventilation facilities and drainage suffices to explain the diminution in the phthisis death-rate. According to the author, the absence of improvement with regard to meat and milk supply goes far to account for the death-rate remaining stationary in tubercular disease of the digestive tract. The foods which, for the most part, are the sources of tubercular infection are meat and milk. So far as concerns meat, which is far the less important of the two, the author advises the establishment and exclusive use of public slaughter-houses under administrative control. In these slaughter-houses experts could decide to what extent the flesh of tuberculous beasts was unfit for human food. It is interesting in this connection to note that beasts bred in confinement—*i.e.* with a diminished fresh air supply—are most frequently the subjects of tuberculosis, the disease in wild animals being very rare.

The second lecture is practically devoted to the consideration of milk as a source of tubercular infection. The vast majority of cases of tabes mesenterica (tubercular disease of the intestines) occur at precisely that period of life which corresponds to the maximum milk consumption, viz. early childhood. The deaths under one year of age, returned as due to this cause, amounting to no less than 1·046 per million births. This, according to the author, is in great part due to the prevalence of tuberculosis among milch cows. In England and Wales there are 2,100,000 milch cows, and of these 525,000 are tuberculous. The rejection of al tuberculous cows is impracticable. The administrative control of cow-houses, especially with regard to the amount of cubic space per cow, would, according to the author, greatly lessen this appalling amount of disease. So long as the cow-house remains filthy, the burnished cleanliness of the dairy is unavailing.

The third lecture discusses the *pros* and *cons* of the compulsory notification of phthisis, and is of less interest to the readers of NATURE, although of profound importance to the expert.

The space at our command has only enabled us to touch upon a few of the many interesting points in these lectures. A thorough perusal of them will repay both the general and the special reader.

2. This book is an interesting monograph devoted to the study of the importance of stimuli of various kinds in different disorders of the nervous system. The author's contention is that the effect of the various stimuli, such, for instance, as massage, friction, electric stimulation, &c., which are now used very generally therapeutically, can be explained physiologically, and therefore that these methods must be regarded as part of the legitimate *repértoire* of the physician.

The first chapter is devoted to the physiology of the subject. The author adopts the neuron theory of the nervous system, and goes a step further in that, according to him, each anatomical unit is also a unit physiologically. The unit of nerve activity he terms the neuron wave (Neuronschwelle). Chapter ii. treats of the pathological changes in the neuron waves. A relatively small part of the book is devoted to the explanation of how external stimuli, applied with a therapeutical object, act in certain cases of hyperæsthesia and paralysis. The author thinks that the effect of external stimuli in these conditions is not entirely explained by merely assuming that they form the afferent impulse of a vascular reflex action, but that they also act by disturbing in one or other direction the equilibrium of the excitations (Erregungen) at the time existing in the nervous system. In conclusion, the author considers that the varied phenomena occurring as the result of so-called "suggestion" are all explicable upon this "physiological neuron" hypothesis, and hence are robbed of any mysticism which, from a legitimate medical practice standpoint, seriously restricted the use of this method.

The monograph is to the general physiological reader

somewhat abstruse, and the style involved, but should be of considerable interest and importance to the neurologist.

3. This report contains a mass of interesting fact; the parts of it, however, most likely to be appreciated by the readers of NATURE are the reports contained in Appendices A and B. These are generalised in the report proper as Auxiliary Scientific Investigations. One of the most interesting of these treats of the relation of enteric fever to oysters. The Medical Department was successful in tracking at least twenty-six cases of enteric fever to infection by Brightlingsea oysters. It was also ascertained that, during 1897, infectious matters derived from persons suffering from enteric fever must needs have been discharged in the immediate neighbourhood of certain oyster beds situated in Brightlingsea Creek. The Urban District Council of Brightlingsea are now taking measures which will obviate this pollution of their oyster-beds.

Dr. Klein reports upon bacillus enteritidis sporogenes. This anærobic bacillus occurs under certain conditions in milk, and has a casual relation to infantile diarrhœa.

Dr. Sidney Martin furnishes a report on the viability of the typhoid bacillus in virgin and organically polluted soil. This research, so far as concerns the ability of the typhoid bacillus to thrive in soils containing other bacteria, is at present incomplete.

A short report deals with the relative values of the chemical and bacterioscopic methods of water analysis; from this it appears that, in the case of waters very slightly contaminated with sewerage, chemical methods gave negative results when bacilli could be detected in probably harmful quantity.

Some further interesting observations upon the streptococcus scarlatinæ have been made. It appears that this organism, which is the cause of scarlatina, may haunt the nasal secretion of patients long after desquamation has ceased and recovery has taken place.

4. The "Contemporary Science Series," so well known to the general scientific reader, has, in including this work in its publications, acted very wisely. It is quite impossible in a short notice, like the present, to give any adequate account of the contents of Dr. Gillespie's book. The subject is treated from a thoroughly scientific standpoint, and yet at the same time is made essentially readable even to the general reader. The only two faults to be found with the book are that, firstly, it is too condensed, and secondly, no doubt for the sake of saving space, the complete references to the literature of the subject are not always quoted. Names are from time to time mentioned without the full reference. This fault is somewhat accentuated by the absence of a bibliography, the mere list of authors being actually of little service. The book is thoroughly up to date, and although there is no attempt at making it in any sense a practical handbook, sufficient of the practical is introduced to give point and interest to the descriptive.

In the chapters upon such subjects as foods, alcohols, &c., the author shows a wise discrimination, and does not allow himself to be the mouthpiece of any of the many varieties of faddism which exist. A biological survey of digestion such as the present, containing a description of digestion in plants, as well as in animals, is certain to be of value to the biologist. The chapter on ferments contains an account of the most recent researches in this field. Numerous diagrams and tables, the latter containing a mass of information, add to the value of the work.

5. Dr. Haig's book may be regarded as an appendix to the author's earlier work on "Uric Acid." Many of the views expressed therein, and reiterated here, are not generally accepted either by physiological chemists on the one hand, or by physicians on the other. It is well to make this fact quite clear, as the general reader, into whose hands this book will probably fall, may be apt to think that what the author states as "shown" or "proved" in "Uric Acid" is universally accepted fact. The obstruction of the peripheral capillary circulation by uric acid may be quoted as an instance of this; it is well to emphasise the fact that this is pure imagination. Further, the poisonous properties ascribed to uric acid and the xanthins are by no means established. To the readers of "Uric Acid," such expressions as "a rush of a lot of uric acid into the blood" will be familiar. "A lot" of uric acid has never been demonstrated in the blood under any circumstances, and such an expression must be regarded as highly unscientific and misleading. Upon premises akin to the above and a few experiments, the author recommends what may be termed ultra-vegetarianism; that is, a vegetarian diet from which eggs are excluded, also tea, coffee, alcohol and tobacco. The book is written in a popular style, and it is to be feared that the plausibility of the manner and the attractiveness of the title, by increasing the circulation of the book amongst the public, will tend rather to the perpetuation of faddism than to the advancement of knowledge.

6. This work is a critical and an historical inquiry into a subject which *ipso facto* is of universal interest. The author lays great stress upon the stringent nature of the proof which must be exacted in the case of any claim to having acquired very advanced age. The methods adopted by the Institute of Actuaries may be regarded in this respect as a standard. Some score of examples of centenarians, authenticated beyond all doubt, is given; but the author rejects such instances as William Parr, to whom tradition ascribes the age of 157 years, as unproved. An interesting chapter is devoted to a consideration of the enormous age of the Biblical patriarchs, various hypotheses being advanced in explanation of this. The book concludes with some interesting speculations concerning a possible law of longevity. The author has taken considerable pains to sift well the literature of his subject, and if the whole is not as concise as perhaps it might be, the book contains much that is interesting and instructive.

F. W. T.

## ROUTH'S DYNAMICS OF A PARTICLE.

*A Treatise on the Dynamics of a Particle.* By Edward John Routh, Sc.D., LL.D., M.A., F.R.S., &c. Pp. xi + 417. (Cambridge University Press, 1898.)

THIS treatise is intended for the student. It has all the merits as well as the limitations which characterise Dr. Routh's other well-known text-books; and, on the principle of reserving the good wine to the last, we will first consider its limitations, more particularly as an introduction to dynamical science.

It is, however, a doubtful point whether the author intends this treatise to be an introduction; for, although he gives, on p. 3, the usual *elementary* demonstration of the "parallelogram of velocities," he continues:—

"This rule is the same as that given in statics for compounding forces which act at a point. Hence all the rules of Statics, which are derived from the parallelogram of forces, will also apply to velocities. We may therefore infer the triangle of velocities, and all the various rules for resolving and compounding velocities, both by rectangular and oblique resolutions."

The logical conclusion from this remarkable demonstration is that the student is supposed to have studied statics before he has ventured into the shiftier ways of what Dr. Routh calls dynamics. This, of course, is not the Newtonian method; yet the whole fabric is avowedly based on the laws of motion. Fortunately, the student able to enter upon a study of this book is, in all probability, well-grounded in the fundamental principles of dynamics, and will skim through the opening sections too quickly to suffer serious contamination. The very first section will, nevertheless, certainly startle him, for there he learns that

"the science of dynamics is divided into two parts. In one the geometrical circumstances of the motion are considered apart from the physical causes of that motion; in the other the mode in which the motion is produced by the action of forces is investigated. The first is usually called *kinematics*, the second is called sometimes *kinetics* and sometimes *dynamics*."

It passes comprehension that a mathematical writer dealing with the most exact of the exact sciences should have the audacity to adopt a nomenclature which virtually makes the part equal to the whole. The source of the confusion is obvious enough. It is a result of halting between two opinions. The expressive word kinetics is adopted, but statics is ignored as a *branch* of dynamics.

The same clinging to the inconvenient and occasionally illogical nomenclature of a past in which Newton was only half understood is noticeable in other parts of the book, and recalls irresistibly Maxwell's verse:

"The phrases of last century in this
Linger to play tricks—
*Vis Viva* and *Vis Mortua* and *Vis Acceleratrix*."

Dr. Routh has a strong affection for *Vis Viva*, in spite of the fact that physically it is half this quantity that is the important thing. To be thoroughly consistent he should call twice the potential energy *Vis Mortua!*

A short section is devoted to so-called *accelerating force*, the origin of which is explained in a rather curious way. It is derived from the equation $F = mf$, and is stated to be the quotient $F/m$. "It is equal to the acceleration, and the word 'force' appears to have been added merely to show from which side of the equation the quantity is derived." The author is apparently ignorant of the fact that this unnecessary phrase is a pedantic translation of Newton's Latin term.

In a neighbouring section, we read that "the theory of work is so much used in statics that only a very brief account is necessary here." This brings us face to face again with a serious blemish of treatment. What logical right has Dr. Routh, in laying the foundations of dynamics, to take statical principles for granted? Does not the parallelogram of forces spring directly from the *definition* of force; and is not that definition ultimately kinetic? Moreover, in a *purely* statical problem forces can do no work; and the introduction of the principle of work into statics is a confession that statics cannot be treated apart from kinetics. In the discussion of certain general dynamical principles (*e.g.* what is too commonly called D'Alembert's), it is usual to appeal to the principles of equilibrium, which have already been established on a sound kinetic basis; but such an appeal is obviously out of place in the treatment of dynamic fundamentals.

Dr. Routh's discussion of Newton's laws of motion is probably the least satisfactory part of the book. There is no clear indication of what is really definition and what is experiential inference in these laws. One term at least is introduced before it is defined, and there is, from time to time, a looseness of language inappropriate to a mathematical treatise. For example, speaking of the momentum of a body, the author says "it may be compounded" by the parallelogram law—compounded, what of, or what with? Within four lines Atwood's "machine" is referred to as a "problem" and as an "experiment." Atwood's machine in the concrete is probably useful enough in *illustrating* to immature minds the meaning of inertia and the law of gravity at the earth's surface; but more it *cannot do*, and any quantitative experiment with it is worthless. As a source of problems to vex the pupil, Atwood's machine in the abstract is of perennial value to the weary examiner.

In § 65 we read:

"The law of gravitation asserts that the forces of attraction of the earth on different bodies at the same place are proportional to the masses of those bodies. This is true whatever be the materials of which the body is made. . . . This is an experimental fact which is independent of the laws of motion. . . . The law of gravitation asserts that $g$ is constant at the same place on the surface of the earth. It is sometimes called the constant of gravitation."

There seems to be a subtle confusion here. The *experimental fact* is that the acceleration due to gravity at any assigned place on the earth's surface is the same for all bodies. The laws of motion *then* enable us to make the first statement quoted above. As for the inconstant $g$, what possible claim can it have to the high sounding title of the constant of gravitation? Such a nomenclature has sprung from half knowledge; and, if referred to at all (for which, however, there was no necessity), should have been at once condemned with all the authority of a master.

The impression we gain from a perusal of Chapter i. is that Dr. Routh has never seriously considered the logical foundations of the science of dynamics, and has probably never had to deal with students really beginning their studies. Once he gets fairly into the heart of the subject, he rises for the most part distinctly above criticism. Beginning, in the usual way, with examples of rectilinear motion (Chapter ii.), he passes on to motion of projectiles, constrained motion in two dimensions, motion in two dimensions, central forces, motion in three dimensions, and finishes with a chapter on "some special problems." To each chapter is appended a

selection of examples well fitted to test the student's progress. Many of these examples are of the familiar "academic" character, having little reference to natural phenomena; but from time to time, and particularly in the chapter on central forces, we meet with problems of high interest and importance. The effect of planetary perturbations on comets and the disintegration of comets into meteor swarms may be specially mentioned. Then the question of the stability of orbits is discussed at considerable length.

Here and there, however, a few points seem to call for remark. In § 222, Dr. Routh finds it convenient to introduce the term *vector*. It would have greatly facilitated his earlier work had he introduced the term at the very beginning. The conception of a vector quantity in mathematical physics is one which every student should get as soon as possible. It should be impressed upon his mind from the very start as something fundamental and far-reaching, and not merely as a convenient term enabling us "to avoid the continual repetition of the same argument."

The title of § 135 is "Discontinuity of a centre of force"—a most extraordinary collocation of words, and absolutely misleading. There can be no discontinuity of a *centre of force*; the discontinuity (if the term be used at all) is in the incomplete mathematical expression of the solution.

A certain looseness of expression is also apparent in the titles of §§ 186, 187, which are respectively, "Work of a central *force*," and "Work of an elastic *string*."

In Chapter vii. Lagrange's equations are introduced, and a variety of interesting problems in three dimensions discussed, *e.g.* motion of a particle constrained to move on a tortuous curve or on a surface. The case when the surface is an ellipsoid is investigated at considerable length, several of Liouville's results being introduced as examples for solution by the student.

Chapter viii. is devoted to "Some special problems," a title, however, which is a most incomplete description of its contents.. The brachistochrone may, in a sense, be called a special *problem*, but, as developed by Tait, Townsend and others, its theory is of a very general character, and abounds in *theorems* of great interest. Following this there is a fairly complete discussion of the motion of a particle relative to the earth when the earth's rotation is taken into account—a problem of no small importance. After a few sections on inversion and conjugate functions, the final "special problem" taken up is Hamilton's theory of action. We doubt if any student, not otherwise instructed, could gather from Dr. Routh's pages the great importance of Hamilton's contributions to general dynamic theory. On p. 394 we read: "These are called *the Hamiltonian Equations of Motion*"; but there is no direct reference whatsoever to Hamilton, and in the index, under Hamilton's name, we find references to "Law of force in a conic" and to "Hodograph," but none to "Action"! In a book, one of whose really valuable features is its system of historic notes, such an omission is inexplicable. In striking contrast there is *full* recognition of the merits of Jacobi, who, as Hamilton himself expressed it in a letter to Andrews, "enriched by his comments" Hamilton's theory. One recommendation the student will do well to follow: let him refer to his "Thomson and Tait." The enunciation of Tait's problem (p. 401) contains a misprint which reduces the statement to an absurdity.

It is a reproach frequently cast by literary men that scientific writers lack style. There is not much scope for a cultivation of style in a mathematical treatise, but surely we have a right to expect good English. In the book before us there occurs with painful frequency the fault of the misrelated participle. On p. 7, an indefinite "it" is found "assuming the principles of the differential calculus"; on p. 145, a (dynamic) couple is represented as "remembering" something; on p. 150, the work done by forces is found capable of "selecting some geometrically possible arrangement," and so on.

By way of general summary we may, in conclusion, remark that, although the first chapter is open to serious criticism, and the book is somewhat marred throughout by a looseness of diction, Dr. Routh's "Treatise on the Dynamics of a Particle" is an important contribution to the literature of the subject. To the working student its value is enhanced by a well-selected stock of examples, many of which appear for the first time in a formal treatise. Some of the problems specially considered are of high interest, and the solutions in many cases are of practical value. In a word, the book fully sustains the reputation of its author as an experienced teacher, now bringing forth from his treasure-house things old and new, and appealing to a wider circle of ardent disciples who will be found wherever the English tongue is heard. C. G. K.

## *LABORATORY MANUALS OF INORGANIC CHEMISTRY.*

*Qualitative Chemical Analysis.* By Chapman Jones. Pp. 213. (London: Macmillan and Co., Ltd., 1898.)

*Practical Inorganic Chemistry for Advanced Students.* By Chapman Jones. Pp. 239. (London: Macmillan and Co., Ltd., 1898.)

*Advanced Inorganic Chemistry.* By G. H. Bailey, D.Sc., Ph.D. Edited by William Briggs, M.A. Pp. 333. (London: W. B. Clive, 1898.)

THE first of the above books appears as one of the well-known series of "Manuals for Students." The tradition of these books is that they are not primarily written for a syllabus, but rather that an author has here an opportunity of developing his own ideas, and producing a book which has individuality. We turn, therefore, with considerable interest to this addition to an already abundant literature to see how far the author has contributed anything new or valuable to analytical teaching. As far as we can gather, the great defect which Mr. Chapman Jones believes to attend the study of analysis is that the student's mind is apt to get filled with a knowledge of isolated reactions, whilst really

"the use of such exercises, as are given in the laboratory, is to the would-be chemist exactly what the practising of exercises and scales is to the young musician. The aim is not merely to perform the exercise, but to do it in such a manner that it shall be practice in a thoroughly sound method of work."

It appears, therefore, that Mr. Chapman Jones sets his mind essentially on producing a correct executant.

Further evidence of this appears in the tables of separations, which are printed on parchmentised paper, and open out on each side of the stitching,

"so that if anything is spilled on to the book as it lies open at any of the tables, the result will not be so disastrous as it otherwise might be,"

and the underlying pages will be protected. This certainly suggests scale practising. Taking the author's purpose as he states it, we have carefully read the book and examined the methods prescribed. We believe certainly that the analytical methods are sound; but we should hesitate to say that, in this respect, this book is superior to a dozen others that could be named. It is written undoubtedly by one who has a mature knowledge of his subject, and the processes described satisfy all reasonable requirements in point of accuracy; but we find hardly anything noteworthy in the mode of presenting the subject or in the details—nothing certainly that will warrant us in saying that this is conspicuously *the* book for a sound method. In other respects, it makes no special claim. The sections of "Comparative Remarks" on the elements or radicals of a group are likely to be useful, but as an exposition of the theory of analysis as well as the practice the book leaves much to be desired.

Mr. Chapman Jones' second book is written to suit the syllabus of the Science and Art Department for practical inorganic chemistry in the advanced stage. The analytical part of it is adapted from the work just noticed. The rest includes the preparation of gases and some volumetric analysis. As all the topics of the syllabus are dealt with, the book will no doubt suit its immediate purpose. The mode of treatment calls for remark in one particular only. The preparations are grouped as follows:—Preparation of gases by the use of cold liquids, ditto by the use of hot liquids, ditto by the heating of dry substances, preparations involving distillation, preparations made in solutions. A protest must be entered against a mode of classification so entirely divorced from educational purpose. Even if there were practical convenience in it, which we do not admit, that would by no means justify a sequence of experiments dictated by considerations of merely having this or that piece of apparatus handy for use.

A book entitled "Advanced Inorganic Chemistry," written for "The Organised Science Series," and containing in the preface a statement that a certain liberality of treatment (of chemical physics) is justified by the importance attached in the syllabus to the subject, is calculated to raise prejudice in the mind of a reader. We make haste to say, therefore, that Dr. Bailey's book contains very little evidence, if any, of having been written to conform to a syllabus, or to provide information in that highly compressed and uninspiring form, which until recent times has seemed to prove most suitable for meeting the requirement of the Science and Art Department. The book begins with a short account of the properties of gases, including a good account of Avogadro's hypothesis, of dissociation, and of the methods of determining the composition of gases. In stating that equal volumes of *all* gases . . . contain the same number of molecules, the author, we think, underlines the wrong word. The whole advance made by Avogadro is surely embodied in the word *molecules*: it was not the introduction of the idea of equal numbers (as beginners are so often taught), nor the mere extension of an existing generalisation. The chapter on the atomic weights of the elements is excellent in most respects, but we regret to see the statement that a measure of the chemical attraction or affinity exerted between two elements is afforded by the heat developed by their union. An unqualified statement of this kind is calculated to instil a fundamentally wrong idea of the relationship between heat and chemical affinity. In the main part of the book dealing with the elements and their compounds, the mode of treatment is broad and luminous, and the information is well selected. Some few deficiencies in detail are to be found; but, on the other hand, there are many little features in which the book is an improvement on others of like scope. The following points are, perhaps, worth noting. Cryohydrates are mostly mixtures of ice and salt, and not definite compounds, as implied on pp. 60 and 67. On p. 103, the production of iodine by the action of sulphuric acid on potassium iodide may be better explained by the reducing action of hydriodic acid on sulphuric acid than by the mere decomposition of the hydriodic acid *per se*. The preparation of silicon from silicon dioxide and of boron from boron trioxide by means of magnesium, and also the preparation of silicon hydride, easily demonstrated in test-tubes, are not mentioned, nor is justice done to the energetic properties of boron. The preparation of potassium chlorate by electrolysis of potassium chloride is not mentioned; and though the electrolytic preparation of sodium is described, the figure which illustrates the process is hardly comprehensible. Three useful appendixes on crystallography, spectrum analysis, and chemical calculations, and a series of chemical problems, conclude the book. Owing to some printing accident, the appendix on spectrum analysis ends prematurely in the middle of a sentence. A. S.

## THE MODERN BICYCLE.

*La Bicyclette: sa Construction et sa Forme.* Par Dr. C. Bourlet. Pp. 228. (Paris: Le Génie Civil; Gauthier-Villars, 1899.)

THIS is a reproduction of a series of articles which appeared in vol. xxxiii. of *Le Génie Civil*, and forms, in some measure, a supplement to the author's "Nouveau Traité des Bicycles et Bicyclettes." With the exception of an appendix on the theory of ball-bearings, the present work is non-mathematical in character, and is addressed to all cyclists who take an intelligent interest in their machines. The first chapter is devoted to an historical summary, then follow chapters on the frame, steering, bearings, gearing, change-speed gears, wheels and tyres, tricycles, accessories, and hygiene of touring.

The work is to be warmly welcomed, as adding to the far too scanty independent literature on the construction of the bicycle. We feel somewhat at a loss, however, as to the standpoint to be taken in reviewing the book. In the historical portion many events which, on this side of the Channel at least, are regarded as of primary importance are not even referred to—*e.g.* Kirkpatrick

Macmillan and Gavin Dalzell's construction of a practical rear-driver, the appearance of the original Dunlop pneumatic tyre with outer cover cemented to the rim, while free-pedals are merely referred to as incidental accompaniments of automatic brakes. Dr. Bourlet's history of the introduction of pneumatic tyres reads like a burlesque :—

". . . The first pneumatic tyres were very timid attempts, and at the best only suitable for racing tracks. . . . The single tube tyres, Clincher, Boothroyd, and others then became popular, and were a little more trustworthy. . . . It was not until Michelin put on the market his detachable tyre that pneumatic tyres entered the domain of practical cycling mechanics. . . . Six months later the Dunlop Company exhibited a detachable tyre. . . ."

Again, in the purely descriptive portions of the book many important developments of the last three or four years are entirely unnoticed ; to wit, Lloyd's cross-roller gear, the Fleuss and Trench tubeless tyres, jointless hollow rims, short-pitch roller chains, the Bowden brake transmitting mechanism ; in fact, the book is at the date of its publication several years behind the times, as far as the bicycle in England is concerned.

The discussion of the various points of construction are very interesting and instructive ; but the conclusions drawn by the author are in many cases diametrically opposed to opinions widely held on this side of the Channel. The author has proved that, for ease of steering, the frame of a good bicycle should be as short as possible ; the frame with extended wheel-base "était donc détestable ; il manquait d'ailleurs de rigidité." The frame of the Pedersen bicycle, weighing less than 20 lbs. complete, receives most praise ; but the author would improve it by substituting pin-joints for the rigid lugs. Mr. Mushing's analysis in the Centaur Company's catalogue of the weight of a bicycle equipped as a heavy roadster and as a road racer (total weights 36 lbs. and 25 lbs. respectively, weight of frame and front forks in each case 7 lbs. 15 oz.) might modify the author's opinion on this point.

In chains, a retrograde movement was effected when, in 1895, English makers returned to the detestable block chains, "un peu modifiées, il est vrai, mais toujours aussi mauvaises." Now, whatever be the merits of the 1899 roller chains, the old inch-pitch roller chains were much worse than the block chains which superseded them. Has the author compared, say, a Hans Renold block chain with the roller chains made prior to 1895? The type of roller chain held up for admiration is that with each sleeve split at the middle, a half-sleeve being made as a solid internal projection from each inner side-plate. This construction is thoroughly bad, and no chain made in this way is durable, as some chain-makers have found to their cost.

A great number of two-speed gears are described, none of which have been sold to any extent in England, while the few two-speed gears known here are not referred to. This chapter is therefore of interest mainly to the mechanician and the designer.

As a practical guide to the cyclist in choosing a new machine, the book will be of most service in France, but of little or no value here. A. S.

## OUR BOOK SHELF.

*The Spirit of Organic Chemistry.* By Arthur Lachman, B.S., Ph.D. With an Introduction by Paul C. Freer, M.D., Ph.D. Pp. ix + 229. (New York : The Macmillan Company. London : Macmillan and Co., Ltd., 1899.)

The title of the book, if it conveys a definite idea, scarcely explains the contents. The preface, however, sets forth the various objects which the book is intended to accomplish. Its main purpose, we are told, is to supplement the text-book and to introduce the student to the current literature of the subject, from which it is to be inferred that he will be equipped with a sufficient knowledge of present problems to follow contemporary research.

The volume consists in reality of a series of essays on subjects which have at one time or another engaged the attention of chemists. It is divided into chapters, the heading of each furnishing the text for a discourse on some prominent theory or classical investigation. "The constitution of acetoacetic ether" leads up to an account of *tautomerism*. The constitution of the sugars, of maleic and fumaric acids, of the oximes and of the diazobenzene compounds, involve a series of dissertations on stereochemical problems ; whilst the chapters on uric acid and the constitution of rosaniline record the development of certain branches of synthetic chemistry. An essay on the constitution of benzene, and a brief history of "Perkin's reaction," complete the series. The subjects are not by any means exhaustively treated ; but they are presented in an easily readable form, and controversial matters are handled in a judicial spirit.

Whether these few essays will enable the student to follow current literature is another question. A great amount of organic research is now busy with the constitution of the terpenes, the camphors, the alkaloids, the artificial and natural colouring matters, and many other subjects of which no word is said. Moreover, several of the subjects discussed have passed into history. Still, there will doubtless be many to whom the volume should prove interesting and profitable reading.

The introductory chapter does not add substantially to the value of the book. Its rather high-sounding phrases convey little real information, and the historical references are too brief to be intelligible to any one ignorant of the history of the science. J. B. C.

*Elementary Physics and Chemistry. First Stage.* By Prof. R. A. Gregory and A. T. Simmons, B.Sc. Pp. viii + 150. (London : Macmillan and Co., 1899.)

The importance of experimental science teaching in elementary schools is being more and more recognised by the Education Department every year. This tendency is seen in the course of elementary physics and chemistry for the upper standards, which was introduced into the Elementary Education Code for 1898. To meet the want thus created is the purpose of the present book, covering the first of the three parts into which the syllabus is divided. The plan of the book is admirable, and though the division of each lesson into "what to do," "reading lesson," and things "to be remembered," involves a certain amount of repetition, there will be compensation to young students in the resulting clearness. Matters are so arranged that the lessons are suitable for classes in which each pupil can perform the experiments for himself, or for those in which they can be made by the teacher alone. In their anxiety to secure a logical sequence of thoughts, the authors have included a few experiments, the results of which we think might have been taken for granted ; but, apart from this, the book seems well adapted for beginners in science. The clear and simple language, combined with a large number of excellent illustrations, can surely leave no doubt in the mind of the dullest pupil as to the ideas which are intended to be conveyed.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### Mangroves Growing in Japan.

HAVING resided for some years in the eastern part of Japan, and having travelled from time to time in various parts of the island of Kiusiu, and from thence to the Farther Isles within the southern boundary of the Luchuan Archipelago, I have noticed that the tropical and sub-tropical types in the Japanese flora are much more marked than has hitherto been supposed. As an instance of this, a selection from the types of mangroves will probably be of more interest, not only to botanists, but also to all lovers of nature, than a list of plant-names.

FIG. 1.—Thickets of *Kandelia Rheedii*, Wight et Arn., growing together with *Pinus densiflora*, Sieb. et Zucc., found on the sides of a stream at Kiiré in Satsuma, Japan. (Reproduced from an original photograph taken by Prof. K. Mitsukuri.)

The northernmost limit of the mangroves in Japan is found in the coast of Kiiré at Satsuma in Kiusiu, where the only species represented is *Kandelia Rheedii*, Wight et Arn. The occurrence of the mangrove in that place is of high interest to geographical botany, inasmuch as that familar representative of tropical vegetation is found there actually intermingled with that of the temperate flora, *Pinus densiflora*, Sieb. et Zucc. This curious and interesting combination is shown in the accompanying illustrations, which were reproduced from the original photographs by Prof. K. Mitsukuri of the Imperial University of Tokyo. Fig. 1 is a fair representation of an outlet of the stream along the coast in the Bay of Kagoshima. Both sides of the stream are studded here and there with the low thickets of *Kandelia Rheedii*, Wight et Arn., among which the evergreen *Pinus densiflora*, Sieb. et Zucc., stands with its outstretching branches. A little further along the coast discloses a finer view (Fig. 2) of the mangrove, forming dense thickets in front; on the background upon the ridge of the hill, a range of *Pinus densiflora*, Sieb. et Zucc., is seen in the distance.

FIG. 2.—View of the coast near Kiiré with the thicket of *Kandelia Rheedii*, Wight et. Arn., in front.

Coming to the island of Amami-Ōshima, the mangroves are common. Here, besides *Kandelia Rheedii*, Wight et Arn., another interesting species, *Bruguiera gymnorhiza*, Lam., makes its appearance. I may here state that Döderlein was, I believe, the first European botanist who collected these species in Japan (vide *Botanisches Centralblatt*, viii., 1881, p 30, and Engler's *Botanische Jahrbücher*, vi., 1885, p. 63).[1] If we proceed again and come to the island of Uchinā or the Lūchū Proper, and from thence to the Yayeyama Archipelago, which is situated close to Formosa, we find in these islands an additional species, *Rhizophora mucronata*, L. It is in the Yayeyama Archipelago that the mangroves exhibit their full development. In the island of Irumuti, the largest among the Yayeyama Archipelago, they often exceed ten feet in height, and exhibit the characteristic feature of the "mangrove forests" (*Mangroven-Wälder*) of the tropical coasts, so admirably described by A. F. W. Schimper ("Die indo-malayische Strandflora," Jena, 1891) and by Karsten ("Ueber die Mangrovenvegetation in malayischen Archipel," Cassel, 1891). Besides, *Avicennia officinalis*, L., and *Sonneratia alba*, L., the well-known associates of the mangroves, are now recorded to grow in the Yayeyama Archipelago.

I observed, in the last-mentioned archipelago, that the fruit of the mangroves when ripe, produces, as is well known, hypocotyl, which soon develops and elongates, and that, in *Rhizophora mucronata*, Lam., it usually becomes 20-40 cent. or more, when the fruit drops on the ground and becomes transfixed. I may also confirm the statement made by Warming (in Engler's *Botanische Jahrbücher*, iv., 1883, p. 519) against the well-known notion that in mangroves the roots produced from the ripe fruits *on* the trees hang down in the air, in the manner of banyan trees, and develop until they reach water, penetrate the mud, and become in time independent trees.

Thus we observe that the three species of the mangroves are at present known to grow in Japan. In conclusion, I may here remark that the thickets of *Kandelia Rheedii*, Wight et Arn., found at the mouth of the river Yawata as well as at the coast between Nukumi and Mayenohama in Satsuma in the Bay of Kagoshima, and also those at Kashiwabara in Osumi, all of which being situated between 31° 18′-31° 23′ N. lat., are, I think, the northernmost limit hitherto known of Rhizophoraceæ.

Tokyo, April 13. TOKUTARO ITO.

### The Development of the Tuatara.

IN the last number of the "Anatomischer Anzeiger" received in New Zealand, there is a paper by Dr. Schauinsland on the development of the Tuatara, confirming the results obtained by Dr. Dendy. A preliminary account of these results has already been published in the *Proceedings* of the Royal Society (vol. lxiii. p. 440), to which Schauinsland makes no reference, although they have been reported in NATURE, while the more detailed memoir was accepted by Prof. Lankester for publication in

[1] The more technical account concerning the determinations of these specimens collected by Döderlein will be published elsewhere.

the *Quarterly Journal of Microscopical Science*, and is, no doubt, by this time in the hands of zoologists.

But it is mere justice to my friend, Prof. Dendy, to place before our European colleagues the following facts in regard to Dr. Schauinsland's reference to the inactivity and lack of enthusiasm exhibited by Colonial zoologists in the matter of this most interesting member of our local fauna.

The Tuatara is quite properly "protected" by the Government of New Zealand; permission to obtain material for the investigation of its life-history was granted to Dr. Dendy, and the lighthouse-keeper on Stephen's Island, a Government servant, was permitted to collect the eggs and embryos for him. But subsequently, and without any communication with Dr. Dendy, and before he had obtained more than a few (if any) eggs, the Government also gave permission to Dr. Schauinsland to collect eggs, and moreover instructed their servant on Stephen's Island to give him every assistance.

In this instance, then, Dr. Schauinsland's charge of lack of enthusiasm is not only baseless. but wanton.

The following fact is not without bearing in this connection. A certain foreign zoologist was recently on a visit to New Zealand for the purpose of collecting the rarer and more characteristic animals, amongst others the Bulimoid pulmonate, *Placostylus bovinus*. Having obtained all the individuals living, as well as shells only, on which he could lay his hands, he proceeded to crush all the young ones he could see, and was heard to remark that if any future zoologist or conchologist wished for a specimen he would have to go to a certain town in Europe (and not to New Zealand).

Dunedin, N.Z., April 13. WM. BLAXLAND BENHAM.

## THE GIPSY MOTH, AND ITS INTRODUCTION INTO AMERICA.

MANY persons, whether entomologists or not, must have noticed a rather slender, dark-coloured moth with feathery antennæ flying among bushes on the continent; and a much larger, stout-bodied, whitish-grey moth, sitting on hedges, or on the trunks of trees. Dissimilar as these insects may appear, they are nevertheless the male and female of the Gipsy Moth (*Porthetria dispar*), the male of which flies about in the day-time like that of the Vapourer Moth (*Notolophus antiquus*), a small tawny-brown moth with a white spot on the fore-wings, which has an apterous female, and the caterpillar of which feeds on a great variety of trees and shrubs (Fig. 1).

The two moths are not distantly related, both belonging to the family *Liparidae*, but while the Vapourer Moth is so common with us that it is often seen flying even in the streets of London, wherever there are any trees near, the Gipsy Moth is now so rare here as to be thought to be extinct in England, though it is abundant, and often destructive, on the continent. The entomologists of the last century speak of it as very rare in England, and as having been introduced into the orchards of Chiswick, where, however, it failed to establish itself. Subsequently, Stephens wrote that it was rare in the neighbourhood of London, though it had been taken occasionally at Coombe Wood, but that it was abundant in the fens of Huntingdonshire. It is very singular that several insects of general distribution on the continent, among which we may specially mention *Papilio machaon*, *Lycaena dispar*, and *Porthetria dispar*, should have ound their last stronghold in England, like the Britons and the Saxons, in the fens, though the Gipsy Moth was formerly common in fens which are still undrained, as well as in some which no longer exist. It is also remarkable that the English fen-specimens of both the butterfly and moth named *dispar* were much larger and finer on an average than the continental representatives of the same species; and that both should have become practically extinct in England since the drainage of the fens.

In 1857, Stainton wrote of the Gipsy Moth: "This species is apparently less common here than formerly," and mentioned Halton in Buckinghamshire, and Stowmarket in Suffolk, as localities. After this time, the moth became rapidly scarcer, and I am not aware that any authentic British specimens have been taken of late years, though a degenerate breed of British origin was preserved among entomologists for a long time, and may be still.

Far different has been the history of the Gipsy Moth in America, where it is not indigenous, though the insect extends across the northern part of Asia-Europe from England to Japan, and is abundant, if not destructive, in most parts of its range.

Thirty years ago, a French entomologist, named Leopold Trouvelot, was living at Medford, in Massachusetts. He was engaged in carrying on a series of experiments on rearing moths, which he thought might possibly be made useful as silk producers. Among other species, he imported the Gipsy Moth, and, by some accident, some of the insects escaped from his custody into his own or the neighbours' gardens. The most

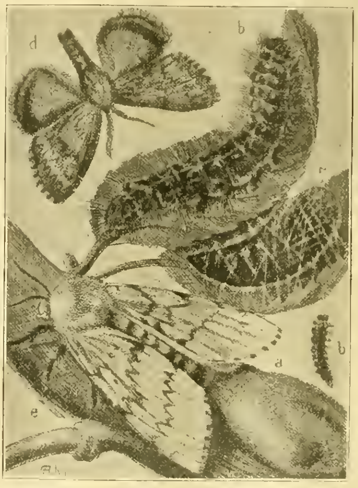

FIG. 1.—Gipsy Moth: *a*, egg mass; *b*, caterpillars; *c*, chrysalis; *d*, male moth; *e*, female moth. (Reproduced from "Insects: Friends and Foes." By Dr. W. Egmont Kirby. Partridge and Co.)

probable story is that some eggs were blown out of the window, and that M. Trouvelot was much concerned at not being able to find them; for the female is a very sluggish insect, which is seldom or never seen on the wing.

Had prompt measures been taken, the insect might possibly have been exterminated; but it does not seem to have attracted any attention till about 1880, when the people then living in or near M. Trouvelot's former residence began to be troubled with swarms of caterpillars, though what they were, and whence they came, was then unknown. For several years the neighbouring houses suffered severely, apple- and pear-trees and shade-trees being stripped of their leaves and killed, and the caterpillars creeping all over and into the houses. Nevertheless, they spread very slowly along the street, and into the surrounding woods till 1889, when the insects multiplied so much that the caterpillars stripped all the trees in the immediate neighbourhood of M. Trouvelot's old house, and then marched forth in

armies sufficient to blacken the streets, in search of fresh provender. A terrible account of the ravages of the caterpillars is given by those who witnessed them, and the town became thoroughly alarmed. Specimens of the insect were sent to the Agricultural Experiment Station at Amherst, Massachusetts, where it was identified by Mrs. C. H. Fernald and her son, in the absence of Prof. Fernald, who happened to be travelling in Europe at the time. On his return, he at once visited Medford, and recommended spraying all infested trees with Paris Green, an arsenical preparation which had previously been employed with great success in checking the ravages of the Colorado Potato Beetle. A pamphlet containing descriptions and figures of the insect in all its stages, with hints for its destruction, was printed and largely circulated; and the veteran agricultural entomologist, Prof. C. V. Riley, gave it as his opinion that if Prof. Fernald's recommendations were carried out at all strictly, there was little fear of the insect spreading, and that it might be entirely exterminated with the expenditure of a little time and money.

Fig. 2.—Destroying the eggs of the Gipsy Moth in the Middlesex Fells Reservation.

In March 1890 a Commission was appointed with full authority to take any necessary measures for the destruction of the pest, and a sum of 25,000 dollars was placed at the disposal of the Commissioners, any person convicted of knowingly spreading the insect, or interfering with the work of the Commissioners, being rendered liable to heavy fines or imprisonment.

As soon as the Commissioners had made a preliminary investigation, it was discovered that the infested area was far larger than had been supposed, and that the grant of 25,000 dollars was wholly insufficient. Large quantities of eggs were destroyed, brushwood cleared, and trees sprayed with Paris Green, while the principal roads leading from the infested district were guarded by policemen, whose duty was to see that caterpillars should not be carried about by passing vehicles.

In 1891, a fresh Commission was appointed, under the auspices of several of the most eminent American entomologists, and Prof. C. H. Fernald was subsequently appointed entomological adviser to the Committee. During the first six weeks of the year, three-quarters of a million egg-clusters were destroyed, estimated to contain from three to five hundred millions of eggs.[1] During the fine season, the trees were sprayed, and in autumn egg-gathering again commenced. Seventy-five thousand dollars were spent this year, and, though the insect was not exterminated, its numbers were seriously reduced. By this time, no less than thirty townships were found to be infested with the insect.

Year by year the campaign against the moth has been continued on similar lines, though impeded by frequent delays in the appropriation grants, as well as by the insufficiency of the amounts, and in 1896 Mr. E. H. Forbush (the field director in the work of destroying the Gipsy Moth) and Prof. Fernald published a volume of 600 pages on the insect and its history, from which much of the information in the present paper is derived. We have also just received the "Report of the State Board of Agriculture on the Work of Extermination of the Gypsy Moth," presented to the Senate and House of Representatives of the Commonwealth of Massachusetts on January 1, 1898, and containing an account of the work of the Committee during 1897. From this we learn that the Committee applied for a grant of 200,000 dollars for the work of that year, and the Legislature promptly granted them three-quarters of the amount. Much work was done (Figs. 2 and 3), and infested districts were cleared as far as the amount would permit, but the Committee's recommendation was for "an appropriation of not less than 200,000 dollars a year for a term of not less than five years, and then an appropriation of not

Fig. 3.—Destroying masses of Gipsy Moth eggs on rocks and ledges.

less than 100,000 dollars a year for a term of not less than five years. After this, an appropriation of perhaps 15,000 dollars a year for a period of five years will be required." On this, Prof. Fernald remarks: "The first five years, with the full appropriation of 200,000 dollars a year, will reduce the territory to such an extent that

[1] These eggs are laid in clusters and covered with down from the abdomen of the female.

with 100,000 dollars a year for the next five years the insect will be practically exterminated, and the remaining five years will be spent in a careful watch of the entire territory, lest a few insects might have been overlooked in isolated localities. Unless a sufficient amount is appropriated to make a very substantial gain each year, it would be better to abandon the work entirely."

It is perhaps not surprising that, after having already spent half a million of dollars in what many persons, rightly or wrongly, considered the hopeless task of exterminating a single insect, the Committee's application for a continuous grant of 200,000 dollars annually should have met with much opposition. A proposal was made to reduce the amount of the grant for 1898 to 75,000 dollars; but it was successfully resisted, and ultimately the full amount of 200,000 dollars asked for was granted for the year.

Another European moth-pest has lately been introduced into America—the Wood Leopard Moth (*Zeuzera pyrina*), which is at present rapidly destroying the shade-trees of New York. But this insect is still more difficult to deal with than the Gipsy Moth, for its naked yellow, black-spotted caterpillar feeds inside the wood of the trees, like that of the Goat Moth, to which it is allied; whereas the black, red-spotted tufted caterpillar of the Gipsy Moth feeds exposed on the leaves of its food-plants.

Different countries exchange their injurious animals and plants from time to time, but no one can tell beforehand which species are likely to establish themselves and to become injurious. We have seen that the Gipsy Moth had ample opportunities of becoming as injurious in England as in America; but, nevertheless, it has died out.

On the other hand, the Woolly Aphis (*Schizoneura lanigera*), which is one of the worst pests of our apple-trees, is said to have come from America, and is often called the American Blight. The vagaries of plants are equally uncertain. Our common water-cress, a harmless plant enough, one would think, has developed a giant form in New Zealand, which is blocking up the water-courses. In the middle of the present century, an American water-plant (*Anacharis alsinastrum*) was introduced into England by some accident, like the Gipsy Moth into America, when it was called the new water-weed, and caused great trouble for a time by choking up rivers and ponds. Fortunately, however, after a few years the plant seems to lose its vitality, and ceases to become a pest, owing, as is supposed, to the female plant only having been introduced into England, and it therefore propagates by buds alone.

Time will show whether the Gipsy Moth will continue its devastations in America, or whether it will either be exterminated by the energetic measures taken for its destruction, or by the conditions of American life proving ultimately unfavourable to it, notwithstanding its first rapid increase. It is evident that, although we cannot avoid the accidental introduction of injurious plants and animals from abroad, some care should be taken in introducing any which might become injurious into another country. M. Trouvelot's experiments were intended to benefit the silk industry in the United States; but they have resulted in letting loose a pest which hundreds of workers are now striving, at enormous annual expense, to eradicate if they can. Let us hope that their efforts may be crowned with success, for otherwise the whole of temperate North America may suffer more or less severely, as the infested districts of Massachusetts are now suffering.

W. F. KIRBY.

## *THE AUSTRALASIAN ASSOCIATION.*[1]

AN Association for the Advancement of Science which can produce, as the record of one year's proceedings, such a volume as the one before us, is at once an indication that a widely-spread interest in science and a vigorous scientific activity already exist, and a promise of future progress. It is a volume on the production of which the Australasian Colonies may be sincerely congratulated.

The Australasian Association for the Advancement of Science held its first session at Sydney in 1888; it next met in Melbourne in 1890; then in Christchurch (New Zealand) in 1891, in Hobart (Tasmania) in 1892, in Adelaide in 1893, in Brisbane in 1895, and in Sydney again in 1898. We do not know whether the fact that only one meeting was held in the five years from 1893 to 1898 was connected with the commercial difficulties through which Australia has recently passed; if so, we trust that the resumption of meetings last year may be taken as a sign of returning prosperity.

The constitution of the Association and the order of proceedings at the general meetings are evidently closely modelled on those of the British Association. The public proceedings begin with an evening address delivered by the President for the year; on the following days, meetings of the several Sections are held, relieved by evening lectures, including one to "working men," conversazioni and concerts, garden parties (with "the number of invitations limited"), Saturday afternoon excursions, and, to wind up the whole entertainment, excursions going further afield. One who is accustomed to the doings at the annual gatherings of the British Association would find himself familiar with the whole programme of its Colonial counterpart. Perhaps he might find his way into a Section whose name and subject he had not been used to in the old country, but he would find most of them just what he was accustomed to, as the following list of Sections will show, namely:—Section A—Astronomy, Mathematics, and Physics; Section B—Chemistry; Section C—Geology and Mineralogy; Section D—Biology, with the sub-departments Botany and Zoology; Section E—Geography; Section F—Ethnology and Anthropology; Section G—Economic Science and Agriculture; Section H—Engineering and Architecture; Section I—Sanitary Science and Hygiene; Section J—Mental Science and Education.

To review with any completeness a volume of over eleven hundred pages, dealing with the almost unlimited range of subjects covered by the ten Sections here enumerated, is obviously impossible. All that we can attempt is to indicate some of what appear to us to be among its more noteworthy contents.

There can be little doubt that the most serious contribution to pure science contained in it is the "Report on our Knowledge of the Thermodynamics of the Voltaic Cell," by Mr. E. F. J. Love. This is a really admirable account of the results that have been obtained, chiefly by Lord Kelvin, Willard Gibbs, and von Helmholtz, by the application of thermodynamic considerations to voltaic phenomena. These results are deduced simply and concisely, and are discussed throughout in relation to the experimental tests to which they have been subjected by various observers. It would, we think, be welcome to many physicists if this paper were reprinted in some more generally accessible publication than the bulky volume before us.

In his presidential address to Section A, Mr. Baracchi, Government Astronomer at Melbourne, gives a very interesting account of the great International Photographic Survey of the Heavens, and especially of the share in this

[1] "Report of the Seventh Meeting of the Australasian Association for the Advancement of Science," held at Sydney, 1898. Pp. lii + 1161.

work undertaken by the Observatories of Sydney and Melbourne. Another part of his address is devoted to urging the importance of a systematic magnetic survey of the Australasian Colonies,and establishing a permanent magnetic observatory in New Zealand. Among other communications to this Section, we may mention an elaborate account of the Trigonometrical Survey of New South Wales, by Mr. T. F. Furber. This work is apparently being carried out with great judgment and skill. The author gives a comparative table, showing the mean errors of the angles in a large number of surveys carried out in Europe, the United States, and elsewhere, which seems to justify him in saying that "The above figures speak for themselves in showing that our work is probably equal to that done in any part of the world." A tide-predicting machine, described by Captain A. Inglis, seems to be recommended by simplicity of construction; the periodic components are represented by templates cut to accurate sine-curves, with appropriate differences of wave-length, which are all fed through the machine at the same speed.

Naturally Australasian fauna and flora, geography and geology, supply material for a large number of descriptive papers. Among these, "A short Dichotomous Key to the hitherto known Species of Eucalyptus," may be remarked. The author, Mr. J. G. Luchmann, identifies no less than 140 species of this, the most important Australian genus of timber-trees. In connection with this paper, we may mention a timely and very earnest protest by Mr. W. S. Campbell against the wantonly improvident destruction of forest trees which is, unfortunately, so common in Australia, as well as in the United States and Canada.

Some of the fundamental questions of social economy, including the production and distribution of wealth, are ably dealt with by Mr. R. M. Johnston, Government Statist of Tasmania, in a presidential address to the Section of Economic Science and Agriculture. Some of Mr. Johnston's conclusions by no means coincide with what are at present fashionable in certain circles in this country, as will be evident from the following quotation: "It is the country which relatively places the smallest number of hands on the land for the production of food and raw products which has also attained the highest stage of progress. . . . I deny, therefore, most emphatically that whatever distress in the United Kingdom still exists would be lessened by any scheme which would place more hands on the land than its economic conditions demand for the production of food and raw products."

The social conditions of the Colonies apparently encourage a relatively great development of governmental participation in industrial operations. After giving some interesting records of his experience as Engineer-in-Chief of Railways and Public Works in South Australia, Mr. A. B. Moncrieff strongly urges the adoption, by the different Colonies, of a uniform system of preparing estimates and keeping records of public engineering work; for, as he rightly points out, in the absence of such a system it is not possible to institute fair and useful comparisons between the works carried out by the engineers of the different Colonies, such as are needed to promote a healthy rivalry among them. The work undertaken for supplying water for agricultural purposes over large areas of dry country seems likely to have very important and beneficial results. Mr. Moncrieff gives some interesting particulars of these operations, and mentions one boring that has been carried to a depth of 3000 feet, which yields 800,000 gallons per day of excellent water at a temperature of 176° F.

A large proportion of the most interesting papers in the volume, including most of those we have mentioned, are due to men who are at the head of various official departments. If the authors of these papers may be taken as fairly representative of their colleagues, we think there is ground for congratulating the Australasian Colonies on the intellectual quality of their chief officials. It appears clear that these men do not rely for departmental efficiency on a blind following of routine, but on an intelligent recognition of the conditions under which they are placed, and of the true nature of the facts with which they have to deal.

Taking the volume as a whole, it gives evidence of solid progress achieved and assurance of future advance.

## SIR FREDERICK McCOY, K.C.M.G., F.R.S., &c.

IN the death of Sir Frederick McCoy, geological science loses one of its most devoted and enthusiastic disciples, one who in early life was associated with Sedgwick in the preparation of that classic work, the "Synopsis of the Classification of the British Palæozoic Rocks; with a systematic description of the British Palæozoic Fossils in the Geological Museum of the University of Cambridge," a quarto volume published in 1855.

Sir Frederick McCoy was the son of Dr. Simon McCoy of Dublin, in which city he was born in 1823. He was educated at the Universities of Dublin and Cambridge, and intended at first to devote himself to the medical profession, but natural history, and the study especially of fossil organic remains, absorbed his chief attention. When but eighteen years of age he had prepared and published a Catalogue of Organic Remains exhibited in the Rotundo, Dublin. Later on, he assisted Sir Richard Griffith in his researches on the fossils of the Carboniferous Limestone of Ireland, and afterwards they prepared a joint "Synopsis of the Silurian Fossils of Ireland," which was issued in 1846. In the same year, McCoy went to Cambridge to help Sedgwick, and we learn (from the "Life and Letters" of that eminent professor) that the new assistant devoted himself for at least four years "uninterruptedly and with unflinching zeal" to the determination and arrangement of "the whole series of British and Foreign Fossils" in the Museum. In 1850, he was appointed Professor of Geology in the Queen's College, Belfast. Meanwhile, he continued to labour at the great work previously mentioned, and which associates the names of Sedgwick and McCoy in the minds of all students of the Cambrian and Silurian rocks. This work was barely finished when McCoy, in 1854, accepted the newly-founded Professorship of Natural Science in the University of Melbourne.

Apart from the larger works to which he had contributed while in this country, McCoy had published numerous papers dealing with fossil Fishes, Crustacea, Echinoderms, Corals, and Foraminifera. He was indeed well prepared for the arduous and successful labours which he now undertook in a new home. Becoming associated with the Geological Survey of Victoria, he established the "Prodromus of the Palæontology of Victoria; or Figures and Descriptions of the Victorian Organic Remains," issued in decades, and he contributed many palæontological reports for the Survey. He also founded the Melbourne National Museum. His latest contribution to science, "Note on a New Australian *Pterygotus*," was printed in the *Geological Magazine* during the present month.

In 1879, he received the Murchison Medal, which was awarded to him by the Geological Society of London, of which society he became a Fellow in 1852. In 1880, he was elected a Fellow of the Royal Society, and he was one of the first to receive the honorary degree of D.Sc. from the University of Cambridge. In 1886, he was made a C.M.G., and in 1891 he was worthily promoted to be K.C.M.G. It is astonishing to note that, while for fifty-eight years he contributed to palæontological literature, his age at his death in May 1899 should be no more than seventy-six.

H. B. W.

## THE EDINBURGH CHAIR OF PHYSIOLOGY.

THE following is the closed list of candidates for the chair of Physiology in the University of Edinburgh, rendered vacant by the death of Prof. Rutherford: Dr. Wace Carlier and Dr. Noel Paton, Edinburgh; Prof. Reid, Dundee; Prof. Schäfer, London; Prof. G. N. Stewart, Cleveland, Ohio; Prof. Stirling, Manchester; Prof. Anderson Stuart, Sydney.

The Edinburgh chair of Physiology, though founded in 1742, has almost invariably been occupied by physicians —amongst others Cullen, Gregory, Alison, and Rutherford's immediate predecessor, Hughes Bennett. The one striking exception in addition to Rutherford is Allen Thomson, the famous anatomist. Rutherford's time having been largely devoted to teaching, it may be truly said that Edinburgh, from a physiological point of view, has still its spurs to win. Had other counsels prevailed in 1855, Edinburgh might have secured the services of Sharpey, and long ere this been as famous for its physiological as for its anatomical school.

The mistakes of 1855 (when the services of Agassiz, as well as those of the founder of English physiology, were declined) are not likely to be repeated, for it is now sufficiently evident to all concerned that if the Scottish capital is to maintain and extend her medical school, she must fill her Science chairs with men who, in addition to great teaching powers, have gained by their researches a world-wide reputation. As it happens, the Court of Curators, in whose hands the appointment lies, will have the opportunity of largely atoning for the past by placing at the head of the physiological department a pupil of Sharpey's who, by his success as a teacher and worker, has placed himself in the very foremost rank of British physiologists.

In the interests of science and of the great imperial seat of learning, we, with Lord Lister, "venture to express the earnest hope that Prof. Schäfer's paramount claims may receive their due recognition."

## NOTES.

THE second (or ladies') conversazione of the Royal Society will take place on June 21.

AT the next meeting (June 8) of the London Mathematical Society, the President, Lord Kelvin, G.C.V.O., proposes to read a paper "On solitary waves, equivoluminal and irrotational, in an elastic solid." At the previous Council meeting, the election of the sixth De Morgan medallist of the Society will take place, and the announcement of the result will be made to the members present at the general meeting. The presentation of the medal will be made at the annual meeting in November next.

THE International Exhibition of Electricity, organised in celebration of the Volta centenary, was opened at Como on Saturday by King Humbert. His Majesty also opened a national silk industry exhibition, connected with the electrical exhibition. Switzerland was officially represented at the ceremony, and there were also present the Bishop of Como, the Senators and Deputies representing the province in the Italian Parliament, some members of the family of Volta, who was born at Como, a number of scientific celebrities, and a large attendance of the general public. Speeches were delivered by the Mayor, the presidents of the two exhibitions, and Signor Salandra, the Minister of Agriculture, who dwelt on the progress made by Italy in the silk-growing industry.

AN international congress dealing with the prevention and cure of tuberculosis was opened in Berlin yesterday. The Emperor and Empress of Germany are taking the greatest interest in the congress, and her Majesty attended in person at the formal opening of the proceedings in the great hall of the Reichstag by the Duke of Ratibor. Some of the foreign delegates will be presented to the Emperor on Sunday after the termination of the congress. Owing to the Whitsuntide recess, the congress will have the use of the whole of the Reichstag buildings. The *Times* correspondent at Berlin reports that on Tuesday night there was an informal reception of the members and delegates by Princess Elizabeth of Hohenlohe in the main gallery of the Reichstag. The congress will be attended by nearly 2000 persons, including 112 foreign delegates and a great number of unofficial foreign members.

IT is announced in *Science* that Mr. Edward H. Harriman, of New York, has invited a number of scientific men to accompany him as his guests on an expedition to Alaska. The party will leave Seattle about the end of May, on a large steamer chartered and fitted up specially for the expedition. They expect to take the "inside passage" route to Lynn Canal, and then, after visiting Sitka, proceed westward along the coast to Yakutat Bay, Prince William Sound, Cook's Inlet and Kadiak Island. Numerous places will be visited which are out of reach of ordinary travellers, and stops will be made to admit of scientific work. Steam launches, tents, camp outfit, packers, &c., have been bountifully provided, so that the largest amount of work may be done in the shortest time.

PROF. S. P. THOMPSON, F.R.S., will be the president of the Institution of Electrical Engineers for the ensuing session.

PROF. J. A. FLEMING, F.R S., will deliver one of the evening lectures during the meeting of the British Association at Dover in September. He has selected as his subject, "The Centenary of the Electric Current."

THE steamship *Antarctic*, with the members of Prof. Nathorst's Expedition on board, left Stockholm on Saturday for the east coast of Greenland in search of Herr Andrée and his two companions.

THE Russian members of the Russo-Swedish Expedition for taking meridian measurements at Spitsbergen, left St. Petersburg on Sunday. The leader of the expedition is Captain Sergieffsky.

MR. R. W. FORSYTH, Royal College of Science, South Kensington, has been appointed official reporter to the Physical Society.

AT the last ordinary meeting of the Midland Malacological Society, held in Mason University College, Birmingham, on May 12, the president, Mr. Walter E. Collinge, in the chair, Dr. Henry Fischer, of Paris, and Prof. H. A. Pilsbry, of Philadelphia, Pa., U.S.A., were both elected honorary members of the Society.

THE announcement of the death of Mr. G. F. Lyster at the age of seventy-six will be received with regret in engineering circles. Mr. Lyster was for a long period engineer-in-chief to the Mersey Docks and Harbour Board. He was a dock engineer of great skill and resource, and not the least of his achievements was the designing of a system of sluicing by which the docks on the Liverpool side of the river were provided with deep sills and approaches—an advantage which up to his time it was not considered practicable to secure. Mr. Lyster, who on retiring a few years ago was succeeded by his son, became a member of the Institution of Civil Engineers in 1858, and of the Royal Society of Edinburgh in 1886.

IN the House of Lords on Thursday last, Lord Harris moved the second reading of the Oysters Bill, which provides that it shall be the duty of every county and borough council to ascer-

tain the sanitary condition of oyster layings within the county or borough, and for that purpose enables the inspector to prohibit the removal of oysters from insanitary layings. Power is given to the Local Government Board to act in the event of default by the local authority, and another clause provides that Her Majesty in Council may in certain circumstances prohibit the importation of oysters from foreign countries and British possessions. The Bill was read a second time.

THE Technical Education Board of the London County Council is co-operating with the Asylums Committee in offering a valuable scholarship of 150*l*. a year, tenable for two years, for students of either sex (preferably qualified practitioners) to enable them to carry on investigations into the preventable causes of insanity. The lady or gentleman appointed to the scholarship will carry on investigations in the Pathological Laboratory attached to Claybury Asylum. A similar scholarship has been held during the past two years by Dr. J. O. W. Barratt, who has carried on valuable original investigations into the causes of insanity, many of which have been recently published. Dr. Barratt has recently been appointed pathologist at the Wakefield Asylum, and the scholarship which he has held is therefore vacant. Candidates must be resident in London. Application should be made to the Secretary of the Technical Education Board, 116 St. Martin's Lane, W.C., not later than Wednesday, June 7.

THE second engineering conference of the Institution of Civil Engineers will be held on June 7–9. The proceedings will be opened with an address by the president, Mr. W. H. Preece, C.B., F.R.S., in the theatre of the Institution, and the programme includes meetings of sections for the discussion of important engineering subjects, and visits to various works. There will be seven sections, dealing respectively with railways, harbours, docks, and canals; machinery; mining and metallurgy; shipbuilding; waterworks, sewerage and gasworks; and applications of electricity. Among the subjects to be discussed are the following:—Systems of fog-signalling; causes of earth-slips in the slopes of cuttings and embankments of railways, and how to prevent or remedy them; machine tools, with special reference to American and German practice as compared with English; recent advances in locomotive practice; the relative advantages of different kinds of power for tramways, light railways and motor-car traffic; bye-product coke ovens; the influence of casting temperature on steel; the purification of gas and the conversion of chemical residuals therefrom, including the preparation of cyanogen; effect of waves on breakwaters in different depths of water; the design of breakwaters; modern improvements in coal mining: winding from deep mines; modern practice in gold mining; comparative advantages of electricity, compressed air and steam for mining and manufacturing purposes generally; the use of filtered flood-water; sewage-sludge disposal by natural agencies, including the purification of sewage by means of artificial filters; mechanical traction by electricity; economical transmission and distribution of electricity from a distance; methods of electrical transformation; some non-integrating electric meters.

IN reference to the scientific commission which was appointed a short time ago by the Colonial Office and the Royal Society to investigate the mode of dissemination of malaria, with a view to devising means of preventing the terrible mortality which now takes place among Europeans resident in tropical and subtropical climates, Dr. Patrick Manson, chief medical adviser to the Colonial Office, has made a statement to a representative of the Exchange Telegraph Company. Dr. Manson states that Dr. C. W. Daniels, of the Colonial Medical Service, British Guiana (who first proceeded to Calcutta to familiarise himself with the work which had been carried on by Surgeon-Major Ross for determining the relation of mosquitoes to the dissemination of malaria), has now arrived at Blantyre in the Central African Protectorate, where he has been joined by Dr. J. W. W. Stephens and Dr. R. S. Christophers. At Blantyre, all the resources of the Protectorate will be placed at the disposal of the commissioners, who, before their return to London, will probably pay a visit to the West Coast of Africa.

THE Meteorological Council have notified by a special circular that they have determined that the issue of forecasts for the hay and corn harvests, which have been distributed during the last twenty years, can no longer be made gratuitously, but they will be supplied in the usual form to persons desirous of receiving them, on payment of the cost of the daily telegrams (including porterage) during the period over which the forecasts are issued. These special forecasts are issued in the afternoon, and refer to the following day; the results in previous years have been very satisfactory, the success reaching in some cases over 90 per cent.

OWING to the public improvements in the neighbourhood o. Parliament Street, the Royal Meteorological Society has been obliged to vacate its offices in Great George Street and find accommodation elsewhere. The Council have taken rooms at Princes Mansions, 10 Victoria Street, which have been fitted up to meet the requirements of the Society. On Tuesday evening, May 16, the president, Mr. F. C. Bayard, held an "at home" in these new rooms, which was largely attended by the Fellows. An interesting exhibition of instruments, photographs, &c., was arranged in the various rooms, and there were also several demonstrations by the optical lantern. At the monthly meeting of the Society, held on Wednesday, May 17, Mr. H. N. Dickson read a paper entitled "The mean temperature of the surface waters of the sea round the British Isles, and its relation to that of the air." A paper by Major-General Schaw, C.B., on some phenomena connected with the vertical circulation of the atmosphere, was also read.

FOUR pieces of a meteorite which exploded and fell on the eastern slopes of Mount Zomba, British Central Africa, on January 25, have recently been added to the British Museum collection. The stones weigh respectively 14, 17, 19 and 29 ounces. The *Times* states that when the meteorite fell, an explosion was heard at Zomba, the reverberations lasting for a few minutes afterwards. The detonation was also heard at Chiromo, situated about ninety miles south of Zomba, and at Fort Johnston and beyond, a distance of about seventy miles in the opposite direction. Zomba was thus roughly the centre of the district over which the actual explosion of the meteorite took place. Ten fragments in all were found, the largest weighing 5 lbs. 12½ ozs. As far as at present known, the area over which the Zomba stones fell represents about nine miles long by about three wide, but, inasmuch as the fragments collected are only those which were seen to fall close to people or houses, it appears probable that a large number of stones may have reached the earth.

AN ingenious arrangement, invented by Mr. Walter Jamieson and Mr. John Trotter, for controlling the direction of torpedoes by means of ether waves is described in the current number of the *Electrician*. The apparatus takes several forms, although the method of utilising Hertz waves is more or less the same in various models, the difference being in the method of applying opposing currents to the rudder or steering mechanism. A satisfactory arrangement appears to be obtained by means of two solenoids, into which are sucked iron cores, attached to

the rudder head, the core which is sucked in depending, of course, upon the direction of the current received. Two rods, projecting above the surface of the water, receive the waves, and are in circuit with a coherer of special type, which affects a relay in the usual way. The actual processes involved in steering and controlling a torpedo are somewhat as follows. Let a torpedo, containing a suitable combination of the apparatus mentioned, be launched, say, from a vessel containing the necessary sending apparatus as described. Suppose the torpedo goes off its course. Then, by means of a switch an induction coil is supplied with electric current, and waves or oscillations are generated. These, on reaching the torpedo, pass into the projecting wire, and thence reach the coherer. This operates the relay, closing its secondary circuit. An electric current now flows through a "selector" to one of the solenoids, the iron core is sucked into right or left, and the helm is thus turned. When the torpedo has attained a proper course, the switch is opened and the waves cease. The vibration in the neighbourhood of the coherer restores it to the original resistance, the current passing through it becomes weaker and ceases to affect the relay coil, which therefore opens the secondary circuit and allows the helm to fly back to the midship position. A large model of the apparatus has been constructed, and it is said to work with entire success under all kinds of conditions.

THE Corporation of Bath have appropriated the necessary funds for the cost of tablets to be affixed to houses entitled to be considered as historic in their city. About forty tablets are to be put on houses which have been the homes of distinguished men, or are otherwise of historic interest, and the first of these, affixed to a house which was once the residence of Sir William Herschel, was officially unveiled on April 22 by Sir Robert Ball. The tablet is shown in the accompanying illustration, for which we are indebted to Sir Robert Ball. The inscription reads: "Here lived William Herschel A.D. 1780." In a little workshop at the end of the back garden of this house, Herschel made his Newtonian reflector, and it was from this spot that he discovered Uranus on March 31, 1781. The Bath Corporation is acting wisely in taking steps to remind the citizens of the distinguished men who have lived within their boundary, and thus incidentally added to the reputation of the city.

THE *Physical Review* (vol. viii. No. 3) contains an article, by Mr. J. G. McGregor, on the applicability of the dissociation theory to the electrolysis of aqueous solutions containing two electrolytes with a common ion. The author calculates the theoretical relative amounts of the distinctive ions transferred by the current, and compares them with observed values, for certain complex solutions. Another article, by Mr. J. O. Thompson, describes some experiments relating to the fatigue of metals. It was found by Lord Kelvin, in 1864, that a wire which had been kept vibrating for several hours or days, through a given range, and then left to itself, came to rest much quicker than when set into vibration after it had been for several days at rest. The present experiments are designed to prove that when temperature and initial amplitude of vibration are constant, and when the wire is not unduly loaded, the period and logarithmic decrement are also constant.

AN investigation of Röntgen phenomena by Mr. John Zeleny is also described at length in the *Physical Review*. The results show that during conduction through a gas under the influence of Röntgen rays, convection currents are produced in the gas, which in general move towards the electrodes. These currents are caused by the motion of the free charges existing in the gas. During the conduction, there is a rapid fall of potential within 0·1 mm. from the surface of the electrodes. By exposing the gas to Röntgen rays, the electric force acting upon the electrodes is increased.

MR. W. L. SCLATER, the director of the South African Museum, Capetown, is making arrangements for the preparation of a series of handbooks on the zoology of the southern part of

the African Continent, to be entitled "The Fauna of South Africa," which will be published by Mr. R. H. Porter. The first volume, by Mr. Arthur C. Stark, containing Part i. of the birds, will shortly appear; and the second volume on the mammals, by Mr. W. L. Sclater, is in a forward state. The volumes will be of octavo size, and will be illustrated by numerous woodcuts in the text.

FROM the *Gazette of British Central Africa* we are pleased to learn that the Administrator of Northern Rhodesia has proclaimed the large district known as the "Mweru Marsh," lying on the east side of the lake of that name, as a "game preserve," in which no game-animals are allowed to be shot without special licence. This excellent step will, we trust, tend largely to the preservation of the existence of the elephants and other large mammals frequenting that district, which has lately received rather too frequent visits from British sportsmen. The Mweru swamps will be found fully described by Mr. Croad in the *Geographical Journal* for June 1898. He says the elephant-hunting there is as good as any south of the equator.

WE have received from Herr B. Walter a reprint of his paper on the nature of electric sparks, published in *Wiedemann's Annalen*, 66. The method of investigation adopted consisted in photographing the sparks produced by an induction-apparatus on a moving plate. The diagrams thus obtained under various conditions bear some resemblance to photographs of so-called "ribbon lightning," and show that the electric spark does not consist of a single discharge alone, but of a succession of brush discharges each following in the path of the previous one. In one case, the interval between successive discharges was found to be roughly the ten-thousandth of a second.

PROFS. ELSTER AND GEITEL have sent us two papers dealing with their investigations on the nature of Becquerel rays. The experiments appear to negative the view that the source of energy of these rays is to be attributed to other radiations falling on the uranium salts which emit them, and Sir William Crookes' hypothesis that the energy is perhaps derived from the air, seems rendered doubtful by experiments made with uranium salts *in vacuo*. The authors confirm the discovery by M. and Mme. Curie of certain substances derivable from the uranium pitch of Joachimsthal, in Bohemia, possessing the property of emitting these rays in a high degree.

A SIMPLE verification of the principle of Archimedes for gases is described by M. P. Métral in the *Journal de Physique* for April. Two flasks, each of 1 litre capacity, are suspended from the scale pan of a balance. On placing the lower one in a vessel filled with carbon dioxide, the equilibrium is destroyed, but is restored again on filling the upper one with the same gas. To verify the principle for gases lighter than air, the two equal vessels are attached neck downwards by clamps to a horizontal beam suspended from the scale pan of a balance. On lowering an inverted jar of hydrogen over one vessel, equilibrium is broken, but is restored by filling the second vessel with hydrogen.

THE energy of Röntgen rays has been investigated by the Rev. Alexander Moffat by measuring the luminous energy given out by a fluorescent screen when exposed to the rays. This energy is of course very small, but it must be remembered that it only represents 4 per cent. of the energy impinging upon the screen, and also that the interval between two successive X-ray discharges is about 1000 times the period of time covered by the discharge itself. Allowing for these facts, it appears that if the Röntgen rays were continuous instead of intermittent, they would exert an effect 500 times greater than sunlight when falling perpendicularly upon a surface.

COHERERS made of platinum or gold filings do not "decohere" on shaking them up after the electric waves have ceased. The more oxidisable metals do. But as M. A. Blondel pointed out at a recent meeting of the Société Française de Physique, the greatest sensitiveness is attained when the metal is only moderately oxidisable, and good results are obtained with alloys of silver and copper artificially oxidised to a degree which can be easily recognised by the change of tint.

AN interesting and timely paper on milk as a food article appears in *Isis*. It is written by Dr. Schlossmann, and deals with the composition and properties of human and animal milk, and with the means for ensuring a proper supply of what is, with bread, the cheapest and most indispensable of food-stuffs. The adulteration of milk by water may be detected by the presence of nitric acid, which is never contained in undiluted milk. The number of dairies containing only healthy milch cows is very small indeed, but most of the danger may be averted by heating the milk to near boiling point, or by freezing it. One firm near Dresden adds quantities of milk ice to every consignment to keep it cool.

A NEW family of Palæozoic corals is introduced under the name *Moniloporidae*, by Mr. Amadeus W. Grabau (*Proc. Boston Soc. Nat. Hist*, April 1899). In this new family it is proposed to include the genera *Monilipora* and *Ceratopora*, forms found in Devonian and Lower Carboniferous strata. The genus *Monilipora* was established twenty years ago by the late Prof. Nicholson and Mr. R. Etheridge, jun. *Ceratopora* is now described by Mr. Grabau; it appears earlier in time than the other genus, and is less specialised in structure.

MR. LAWRENCE M. LAMBE publishes a series of notes on Canadian Palæozoic corals (*Ottawa Naturalist*, February and March 1899). He calls attention to certain structural details which had previously been overlooked or misinterpreted, and he describes one new species of *Lithostrotion*.

WE have just received vol. iv., No. 3, of "Indian Museum Notes," containing, *inter alia*, an article by Mr. F. Finn, the Deputy-Superintendent of the Museum, calling attention to the abundance of small green *Homoptera* (locally known as "green bugs") in India, and suggesting that they might be imported into England as food for cage-birds. There seems, however, to be some difference of opinion among the bird-fanciers who have experimented with them as to their value; but this may be due to their being more relished by some kind of birds than by others.

*Bulletin* No. 19 (new series), U.S. Department of Entomology, "Some insects injurious to garden and orchard crops, prepared under the direction of the Entomologist, by F. H. Chittenden, Assistant Entomologist," relates chiefly to *Coleoptera* (flea-beetles, chafers, bark-beetles, ladybirds, &c.), *Homoptera*, and *Lepidoptera*. Special attention is called to the squash ladybird (*Epilachna borealis*, Fab.) and the squash bugs (*Anasa tristis*, De Geer, and *A. armigera*, Say), and to the recently introduced moth (*Hellula undalis*, Fab.), a South European species, which has lately been committing serious ravages on cabbage, turnip, and other cruciferous plants in the neighbourhood of Augusta, Georgia.

A DESCRIPTIVE list of recent large scale maps, including both surveys and compilations, together with a list of some large atlases, has been prepared in the Intelligence Division of the War Office by Mr. Alexander Knox, Map Curator, and can be obtained from Messrs. Eyre and Spottiswoode. The volume forms a supplement to "Notes on the Government Surveys of the Principal Countries of the World."

A GLANCE through the new edition of the catalogue of physiological instruments manufactured by the Cambridge Scientific Instrument Company shows the importance of a knowledge of physics to physiologists and biologists, for without an acquaintance with physical principles it would be impossible to design or use many of the instruments described. Special attention may be called to the completeness of the list as regards recording drums and motors, apparatus for blood analysis, and anthropometric apparatus.

SEVERAL important papers appear in volume x. of the *Bulletin* of the American Museum of Natural History, just received from New York. Among the subjects dealt with are: Mexican birds; native tribes of Mexico; new mammals from Western Mexico and Lower California; complete skeletons of *Teleoceras fossiger* and *Coryphodon radians*, with notes upon the locomotion of these animals; extinct Camelidæ of North America and some associated forms; evolution of the amblypoda, revision of the species of Euchloë inhabiting America; the Chickarees, or North American red squirrels; vertebrate fauna of the Hudson Highlands; and the Bombycine Moths, found within fifty miles of New York City.

A THIRD edition, revised and enlarged, of Prof. J. Arthur Thomson's "Outlines ot Zoology" has been published by Mr. Young J. Pentland, Edinburgh. The volume, which contains more than eight hundred pages and 332 illustrations, is an inspiring text-book which students of zoology may use in the lecture-room, museum, and laboratory.—The seventh edition of "A Treatise on Practical Chemistry and Qualitative Analysis," by Prof. Frank Clowes, has been published by Messrs. J. and A. Churchill. The new edition of this successful volume has undergone a thorough revision, and some additions have been made. The organic portion of the book will now meet the needs of many medical students.—Messrs. A. and C. Black have published a second edition of Mr. C. M. Aikman's instructive little book on "Milk: its Nature and Composition." The volume provides students of agricultural science with a capital manual on the chemistry and bacteriology of milk, butter, and cheese.

MESSRS. WILLIAMS AND NORGATE's latest *Book Circular* (Scientific Series, No. 71, May) contains a number of useful descriptive notes on recent and forthcoming scientific books, as well as the usual particulars. Among the announcements, we notice the following:—A new monthly periodical devoted to biological sciences is announced from Italy. The title will be "Revista di Scienze Biologiche," and it will be edited by Enrico Morselli.—The third edition of Beilstein's "Handbuch der organischen Chemie" is now fast approaching its completion, and the final part of the fourth volume will probably be published in the course of the coming summer. The first volume, consisting of 1586 pages, was published in 1893; the second volume, of 2211 pages, in 1896; and the third, of 1020 pages, in 1897.—The new edition of Richter's "Lexikon der Kohlenstoffverbrudungen," which is at present in the press, will contain over 60,000 formulæ. The whole of the 56,000 formulæ which appear in Beilstein's Handbook will be indexed in the work, so that reference from it to Beilstein will be easy. —"Chimie végétale et agricole" is the title of a work by M. Berthelot which is in the press, and will be issued very shortly. It will be in four volumes.—The first volume of a fourth revised and enlarged edition of Dr. G. Lunge's "Chemisch-Technische Untersuchungsmethoden" is in the press, and will be published very shortly. The work will be complete in three volumes.—"Die Einrichtungen zur Erzeugung von Röntgenstrahlen und ihr Gebrauch" is the title of a work by Dr. B. Donatti which is in the press, and will be issued very shortly.—Towards the end of this month, the fourth and final volume of Prof. P. Duhem's "Traité élémentaire de mécanique chimique fondée sur la Thermodynamique" will be issued. The following is a list of its contents: "Les melanges doubles. Statique chimique générale des systèmes hetérogènes." The volume will also contain a complete index.

THE additions to the Zoological Society's Gardens during the past week include two Green Monkeys (*Cercopithecus callitrichus*, ♂ ♀) from West Africa, presented respectively by Mr. J. B. Robinson and Mr. H. Gifford; a Yellow-whiskered Lemur (*Lemur xanthomystax*, ♂) from Madagascar, presented by Mr. C. B. Ayerst and Miss Mary F. Ayerst; a Common Ducker (*Cephalophus grimmi*, ♂), a Banded Ichneumon (*Crossarchus fasciatus*) from South Africa, presented by Mr. W. Champion; a Cinereous Vulture (*Vultur monachus*), South European, presented by H.G. the Duchess of Marlborough; a Black Kite (*Milvus migrans*), European, presented by Mr. G. H. Walker; a Chilian Sea Eagle (*Geranoaetus melanoleucus*), captured off Cape Horn, presented by Captain Bate; six Derbian Zonures (*Zonurus giganteus*) from South Africa, presented by Mr. W. L. Sclater; two Common Snakes (*Tropidonotus natrix*) British, presented by Mr. E. Haig; a Chimpanzee (*Anthropopithecus troglodytes*, ♀) from West Africa, deposited.

## *OUR ASTRONOMICAL COLUMN.*

NEW STAR IN SAGITTARIUS.—The *Astrophysical Journal* for April 1899 (vol. ix.) contains a reproduction of a photograph of the spectrum of this star taken at Harvard College Observatory, together with a picture of a chart plate showing the position of the star on April 29, 1898, when its magnitude was 8·4.

The photograph of the spectrum shows the changes in the spectrum by a comparison of its appearance on April 19 and April 21, 1898. The first shows $H\beta$, $H\gamma$, $H\delta$, $H\epsilon$, $H\zeta$, $H\eta$, and possibly $H\theta$, as bright lines. A broad band at $\lambda$ 4643 is also bright, with several other *narrow* bright bands. These are probably coincident with corresponding lines in spectrum of Nova Aurigæ. The plate taken on the later date shows several important changes, chiefly the appearance of a *narrow bright* line at $\lambda$ 5005, possibly coinciding with the chief nebular line at $\lambda$ 5007.

COMET 1899 *a* (SWIFT).—

*Ephemeris for 12h. Berlin Mean Time.*

| 1899. | R.A. h. m. s. | Decl. ° ′ | Br. |
|---|---|---|---|
| May 25 | 20 48 31 | +54 41·8 | 1·77 |
| 26 | 20 26 33 | 55 47·5 | |
| 27 | 20 3 7 | 56 38·4 | 1·71 |

The comet is now moving very rapidly in R.A., and becoming more favourably situated for observation. During the week it passes in a north-westerly direction through Cygnus into Draco. On the 25th it will be about 10° due north of $\alpha$ Cygni, and on June 1 4° north of $\gamma$ Draconis. It reaches its maximum northern declination on the 29th. Although its brightness has been steadily declining, it is still easily visible to the unaided eye when its position has been ascertained.

## *THE REGISTRATION OF OPTICIANS.*

OBSERVERS of the undercurrents of scientific progress in this country cannot have failed to note during the past twelve months a very remarkable movement at work amongst the opticians, especially amongst the younger men in the optical trades. An intelligent scientific study of the principles of optics has hitherto never been required of the optician, who from the first day of his apprenticeship might grow up in the business entirely untrained in everything save the mere buying and sell-

ing of optical goods. All this is rapidly changing, as indeed was to be desired. Half a century ago, the qualification for practising as a surgeon was practically a mere serving of indentures, while the trade of druggist might be practised by one who had never had any instruction in even the elements of chemistry. There was no organisation to examine the candidates, or to certify them if qualified; there was little stimulus to study. Hence, in the absence of any controlling body, the young men growing up in the optical trades have had little inducement to acquaint themselves with even the elements of the science on which their industry is based. Even those who might be studiously inclined found little to encourage them; for, strange to say, the existing text-books of optics are of little or no use to such. They are written mostly from a different standpoint, to enable University candidates to pass academical examinations, and fail to deal with many of the problems that present themselves to the practical optician. Further, great examining bodies, such as the Science and Art Department and the City and Guilds of London Institute, have never formulated any examinations in optics or optical instrument making.

The present salutary movement has originated quite outside academic circles, having arisen in the ancient London guild called the Spectacle-makers' Company, which, like so many of the old London guilds—the Clothworkers', the Leathersellers', the Carpenters', and the Plumbers' Company—has most laudably devoted of its funds to the promotion of the industry from which it takes its name. The Spectacle-makers' Company is not one of the twelve great Companies holding landed property nor possessed of great wealth. Relatively to the great City Companies, such as the Mercers, Goldsmiths, Fishmongers, Drapers, it is poor. But it has shown much energy and enterprise in organising the certification of opticians. Briefly, what the Spectacle-makers' Company has done is this: it holds at least twice a year examinations in optics, open only to those who have entered the optical trades; and on those who have thus shown a real acquaintance both with the theory and the practice of their trade, it confers a diploma or certificate, and registers them as qualified in optics. It further admits them to the freedom of the guild. The stimulus thus afforded to those in the optical industry in this country has been undeniably very great. Optical classes have been eagerly sought in London, and have also been held in many provincial towns, and a widespread demand for optical literature has sprung up.

The scope of this movement may best be understood by a reference to the official syllabus put forward by the Spectacle-makers' Company. It states that when the Company was granted a Royal Charter in 1629, spectacles were practically the only optical instruments dealt in; but with the progress of science as other instruments were invented, the spectacle-maker became a general optician. With the division of labour which arose, the trade became divided. It is the object of the Spectacle-makers' Company to re-associate with the guild all who possess the necessary technical ability. A theoretical and practical examination must be passed by those candidates who are recommended as eligible by two established members of the craft. The full examination comprises arithmetic, algebra, trigonometry, elementary heat and light, as well as general optics, optical instruments, and spectacles, practical tests in optical work, in visual optics so far as instruments are concerned, and in matters connected with one of the following instruments: the camera, the microscope, and the sextant, at the choice of the candidate. The part of the examination relating to visual optics deals with the general anatomy of the human eye; the course of light passing through the eye and modified by lenses, cylinders, and prisms. It deals also with the simple "errors of refraction," otherwise called hypermetropia, myopia, presbyopia, and astigmatism. It requires a knowledge of trial lenses, test types, astigmatic charts, and the optometer, &c. In the practical tests, candidates are required to execute measurements of focal length, and to verify cylindrical and prismatic lenses; to use the spherometer; to determine the axis of a cylinder and the deviation of a prism; to neutralise simple and combined lenses; to transpose lens combinations; and to centre and adjust lenses and frames, &c. It has been the practice, at the inauguration of similar schemes, to make some exceptions by admitting without examination those men who had long been in practice. But the Committee of the Spectacle-makers' Company decided that even such should be examined; it conceded, however, that down to July 1, 1899, all who had spent seven years in the optical business might be accepted, provided they succeeded in passing that part of the examination which relates specially to spectacles.

The Optical Committee has itself organised classes for optical instruction, and has carefully limited the training so as not to trench on the province of the ophthalmic surgeon. As examples of this case, it may be stated that students are specially instructed that they are not to treat disease, or any case of myopia above seven *dioptres*, but refer such to an ophthalmic surgeon; and so also the cases of children whose punctum proximum is beyond 10 centimetres, or any persons who cannot, when corrected for a simple error of refraction, see 20/20 print.

The first examinations under this scheme were held in November 1898, and they were followed by a second series in March 1899. The examiners selected by the Optical Committee of the Company were Prof. Silvanus Thompson, F.R.S., Dr. Lindsay Johnson, and Mr. G. Paxton of the well-known firm of Curry and Paxton, the latter being assisted in the practical examination by Messrs. A. A. Wood and W. A. Dixey. At each of these examinations over a hundred candidates presented themselves. The examinations were strictly on the lines indicated, no questions being set as to the diseases of the eye, or in retinoscopy, or on matters outside the province of optics proper.

At the outset, it was necessary to guard against any misapprehension as to the scope and nature of the examination scheme, which might have led to difficulties between opticians and ophthalmic surgeons, such as those which in time past have arisen between pharmacists and qualified medical practitioners. Very wisely, it was decided that the examination should be confined to optical matters, and should not treat of disease, nor even of the eye at all save as an optical instrument. The examination is to test candidates solely in matters of optics, so as in no way to interfere in things that lie within the exclusive province of the ophthalmic surgeon. In pursuance of this policy, the application of the ophthalmoscope to the eye, which is a matter for the ophthalmic surgeon, is excluded from the subjects of the examination. On the other hand, the principle of construction of the ophthalmoscope, which is a matter within the province of the optical instrument maker, is included. Recognising that the use of drugs, such as cocaine and homatropine in retinoscopy, is purely a matter for the ophthalmic surgeon, the Spectacle-makers' Company not only excludes from its syllabus of examinations all optical tests implying or requiring their use, but it sternly discourages the idea that an optician should go out of his sphere to meddle with such matters. Nay, further, it requires, amongst the conditions upon which its diploma is held, that the holder shall sign a declaration that he will not use any drugs for the purpose of dilating the pupil.

It is believed that the firm stand thus made officially by the Spectacle-makers' Company will have a beneficial effect in stamping out a practice which—particularly in certain provincial centres—had been growing up of opticians, devoid of any medical qualification, administering drugs such as homatropine, and pretending to make retinoscopic tests that ought to be left to the ophthalmic surgeon. In yet one other direction the certification and registration of opticians will, as it becomes general, promote the interests of the public. There are, unfortunately, in many towns advertising opticians absolutely unqualified scientifically who deceive the public by pretending to impossibilities such as the curing of cataract without operation, and the like. The Medical Acts are unfortunately powerless to reach these; and hitherto the public has had no means of distinguishing between them and the really qualified opticians, since until now there has been no organisation to register the properly-qualified optician. But as the certification of really qualified opticians becomes general, it will be possible to detect and eliminate the quack, whilst the qualified optician will be deterred, at the risk of being disbarred, from issuing advertisements that would mislead the public. Already, even at this early stage, the advantages of organisation have become apparent, the Committee of the Company having already several times been called upon to intervene to insist on the withdrawal of advertisements which might be thought misleading to the public or unfair to other opticians.

The impulse to optical studies has been undeniable, and is certain to spread. The demand of the younger men in the optical industry for optical teaching that will be of service to them will certainly modify the abstract and jejeune courses of scholastic optics offered to them in some of the provincial University colleges, where the optics of the workshop, and even

the methods of optical testing in use in the industry, are practically unknown, and science as well as the public will be gainers by the movement. A debt of gratitude is owing to the Court of the Spectacle-makers' Company, and to its Master (Mr. W. E Thornthwaite) for their efforts. The Company has lately received notable accessions of strength in having admitted to its freedom several of the highest names in science, including the Astronomer Royal, Captain W. de W. Abney, Sir William Crookes, and, last but not least, Lord Kelvin.

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The seventh "Robert Boyle" lecture of the Junior Scientific Club will be delivered by Prof. J. G. McKendrick, F.R.S, in the large lecture theatre at the University Museum, on Tuesday, June 6, at 8.30. The subject will be "The physiological perception of musical tone."

The 201st meeting of the Junior Scientific Club was held on Wednesday, May 17. After private business, Prof. E. B. Tylor, F.R.S., read a paper on the survival of the palæolithic condition of man in the South Pacific region. Mr. R. D. MacGregor (Exeter) also read a paper on Indian butterflies

CAMBRIDGE.—The subject of the Rede Lecture, to be delivered by Prof. Cornu on June 1, is "The Wave Theory of Light: its Influence on Modern Physics."

Admission to the ceremonies in the Senate House, in connection with the jubilee of Sir G. G. Stokes on June 2, will be by ticket. Applications must be made through members of the Senate not later than May 26.

The General Board have proposed the detailed regulations for the Board of Agricultural Studies in connection with the new Department of Agriculture. County and Borough Councils who contribute annual grants to the funds of the Department are to nominate members of the Board.

Honorary degrees are on June 2 to be conferred on Profs. Cornu and Darboux of Paris, Kohlrausch of Berlin, Michelson of Chicago, Mittag-Leffler of Stockholm, Quincke of Heidelberg, and Voigt of Göttingen.

Prof. Newton, who has recently been somewhat out of health, is to depute his lectures in zoology during the ensuing academical year to Mr. W. Bateson, F.R.S., of St. John's College.

Mr. Neville, F.R.S., of Sidney, has been appointed an elector to the chair of Chemistry; and Mr. Larmor, F.R.S., of St. John's, an elector to the Jacksonian professorship, in place or the late Mr. P. T. Main.

THE endowment of a quarter of a million for the University of Birmingham has been secured. At a meeting of the canvassing committee on Thursday last, it was announced that since the previous meeting 24,000*l.* had been promised, and that this, added to the sum previously promised, including the 50,000*l.* from Mr Carnegie and the 37,500*l.* from the anonymous donor, brought the total up to 254,580*l.*, or 4580*l.* in excess of the amount originally fixed upon. The anonymous donor, recognising that the endowment of 250,000*l.*, although sufficient for a starting point, must soon be largely augmented, has offered, if the fund is raised to 300,000*l.* by the end of June, to contribute the last 12,500*l.* The committee have now to find 33,000*l.* to secure the additional 12,500*l.* from the anonymous donor. If this is obtained, it will make 50,000*l.* altogether subscribed by Mr. Chamberlain's friend.

THE following additional endowments and gifts to educational institutions in the United States are recorded in *Science*:—An Appropriation Bill recently passed by the Illinois Legislature gives to the University of Illinois about 600,000 dollars. The Wisconsin Legislature has appropriated for the University of Wisconsin 151,000 dollars, of which 100,000 dollars is for an engineering building. The Colorado Legislature, besides passing a Bill giving its State University an income of one-fifth of a mill on each dollar of assessed valuation, has made grants amounting to about 110,000 dollars. In Nebraska, the State University has been given a one-mill tax, which will, it is estimated, yield about 168,000 dollars yearly.—Columbia University has recently received a gift of 10,000 dollars, to be known as the Dyckman Fund for the encouragement of biological research, the interest of which will be granted to post-graduate students.

THE subjoined table, showing the ratio of the teaching staff to the number of students in ten of the largest universities of the United States, is printed in *Science*. The first column gives the number of persons composing the faculty, including instructors of all grades; the second gives the total number of students enrolled in the institution; the third, the proportion students to teachers.

| | Faculty. | Students. | Ratio |
|---|---|---|---|
| Johns Hopkins | 123 | 641 | 5·2 |
| Cornell | 328 | 2038 | 6·2 |
| Columbia | 303 | 2185 | 7·2 |
| California | 286 | 2391 | 8·3 |
| North-western | 222 | 2019 | 9·1 |
| Harvard | 411 | 3901 | 9·4 |
| Yale | 255 | 2500 | 9·7 |
| Chicago | 212 | 2307 | 10·9 |
| Pennsylvania | 258 | 2834 | 10 9 |
| Michigan | 222 | 3192 | 14·4 |
| Total | 2620 | 24,008 | 9·1 |

## SCIENTIFIC SERIALS.

*American Journal of Mathematics*, vol. xxi. No. 2, April.—On systems of multiform functions belonging to a group of linear substitutions with uniform coefficients, by E. J. Wilczynski In this memoir, the author attempts to prove the existence of certain general functions, studied herein, he believes, for the first time. The existence of a large and important class of these functions is demonstrated by an indirect method, which consists essentially in generalising the hypergeometric functions in a proper manner. The work is connected in a way with the researches of Fuchs, Schwarz and Neumann (on Riemann's theory of Abelian functions, and of Klein (*Math. Ann.*, Bd. 41). Oskar Bolza states that his principal object, in his paper on the partial differential equations for the hyperelliptic $\theta$ and $\sigma$ functions, is to replace part of Wiltheiss's work (*Crelle*, Bd. 99, and *Math. Ann.*, Bd., 29, 31 and 33) by simpler and more direct proofs.—E. B. Van Vleck contributes an article on certain differential equations of the second order allied to Hermite's equation. The treatment is thorough, and the work is accompanied with numerous diagrams.—Note on differential invariants of a system of $m$ points by projective transformation, by E. O. Lovett, shows that to generalise a theorem of Henry Smith's relative to tangent curves (*cf.* on the focal properties of homographic figures (*Proc. London Math. Soc.*, vol. ii.) and the theorem relative to parallel curves, it is only necessary to substitute "surface" for "curve" and "measure of curvature" for "radius of curvature." A second (short) paper by Bolza is entitled "Proof of Brioschi's recursion formula for the expansion of the even $\sigma$ functions of two variables." The author believes that no proof of these theorems has hitherto been published. Brioschi merely stated them in a note (*Goettingen Nachrichten*, 1890, p. 237).—E. Jahnke supplies a two-page note to Prof. Craig's memoir, "Displacements depending on one, two and three parameters in a space of four dimensions."—There is an interesting prefatory notice, from which we learn that Prof. Craig, after seventeen years' connection with the editorial work of the Journal, is succeeded by Prof. Simon Newcomb, who writes this exceedingly modest notice.

*Symons's Monthly Meteorological Magazine*, May.—Ozone, by D A. van Bastelaer. Since 1886, the author has persistently registered the amount of ozone and submitted reports to the Royal Society of Public Health of Belgium, and has also published five-day means throughout the year, with the idea of their being used in connection with the death-rate. Although at individual stations the amount of discoloration varies greatly from day to day, the means remain very steady both for months and for years. Some places, especially Flanders and the neighbourhood of the Ardennes, have constantly much higher means than others. Mr. Symons remarks that it has sometimes been objected that the discoloration of ozone papers is not solely due to the presence of ozone, so that the subject is generally neglected, but there is probably no equally simple and trustworthy indication of the freshness of the atmosphere, and he therefore urges that such records should be kept.

## SOCIETIES AND ACADEMIES.

### LONDON.

**Royal Society**, April 20.—Some further Remarks on Red-water or Texas Fever. By Alexander Edington, M.B., F.R.S.E., Director of the Bacteriological Institute, Cape Colony. Communicated by Dr. Gill, F.R.S.

Since my communication[1] to the Royal Society of London, by Prof. Thomas R. Frazer, I have been able to obtain valuable additional evidence as to the communicability of the disease by the use of blood derived from animals which have been either recovered from the sickness for a very considerable time, or which have been inoculated many months previously to the date on which their blood has been used.

On December 8, 1898, I withdrew some blood from animal No. 18, which has been continuously under observation since it was inoculated on December 22, 1897. After defibrinating the blood, 20 c.c. was used to inoculate a young ox (No. 54) by intravenous injection. On the following day, a sharp rise of temperature occurred, which reached to 106°·6 F. On the following morning it was observed to have fallen to 99°·8 F. Three days later the temperature was again over 104° F., but fell previous to the next morning. From this time onward an erratic course of temperature was observed, and on the twenty-fifth day, subsequent to inoculation, it was seen to be ill; refused food, but had no definite symptoms of "red-water." Three days later it died. The blood on examination was seen to contain the spherical forms of the parasite.

On post-mortem examination, the bladder and urine were quite normal. The liver was not enlarged, but was somewhat discoloured in patches, and the biliary ducts were distended with bile. The bile was much altered, being stringy and of a greenish-yellow colour. The spleen was normal in size and consistence. The kidneys were enlarged, and the pelves were filled up by a yellowish gelatinous exudation. The cortex was somewhat congested, but there was no evidence of any true inflammatory change. The general muscles were pale in colour, and there was slight evidence of jaundice. This experiment serves to show that an animal which has been inoculated with infected blood, while it may not develop much illness as a result of it, is really infected and, moreover, its blood, if drawn as late as a year subsequently, is yet so infective that an intravenous injection of it, into susceptible animals, will certainly infect, and may even kill, although after a somewhat extended period of time.

Very important corroboration of this is furnished by the experience of inoculation for red-water, which has lately been adopted in the Cape Colony. Four animals which were immune to red-water (three by reason of having had the disease and recovered, and one by being born and reared on permanently infected veld) were sent from Fort Beaufort to Queenstown to be used by the veterinary surgeon there for inoculation purposes. The animals to be used for inoculation had been "fortified," *i.e.* re-inoculated with virulent blood, seven weeks previously.

Twenty animals were inoculated with defibrinated blood from one animal, the doses used being 10 to 20 c.c., according to age. All had a febrile reaction and some slight symptoms of the sickness, but easily recovered. From one of the other of the four animals blood was taken and used to inoculate seven head, giving doses of 10 to 15 c.c. These also all had a reaction, but made good recovery.

On November 1, the four animals were re-inoculated with virulent red-water blood, and in each case 5 c.c. was injected intravenously and 10 c.c. subcutaneously. Twenty-nine days later they were bled. With this blood two lots of cattle were inoculated.

One lot consisted of 107 animals which had not ever been exposed to red-water infection. The doses used were increased beyond those which I had recommended, namely, 10 to 25 c.c. were used, according to age. Of these animals no less than seventeen died of characteristic red-water. The remainder made a good recovery.

The second lot consisted of fifty-three head of cattle, all of which with one exception (an imported animal) had been born and reared on red-water veld. The imported animal was the only one which showed any signs of reaction, but it made a good recovery.

This experience has sufficed to show that it is not always safe to exceed the doses which I have recommended, unless the animals which have been used for withdrawing blood have been untouched for at least a considerable number of months.

I have been able, with the co-operation of several farmers, to carry out experiments by which inoculated cattle have been fully exposed to infection at later dates. In May 1898, I inoculated ten head of old cattle with blood from an animal which had been inoculated, six months previously, with virulent blood. These cattle were immediately removed from the Institute, and later sent to an infected area in company with ten head of young animals which were uninoculated, but, as is commonly known in this Colony, are not so liable to death from this disease as are older animals. Of the young stock all have been infected by exposure in the veld, and three have died. Of the older, more susceptible, animals not one has shown the slightest signs of illness, and the cows have given birth to healthy calves.

Mr. J. H. Webber had twenty-eight head of Fish River cattle inoculated on November 7, 1898, and subsequently had them removed to his farm, which is well known to be one of the worst infested areas in the eastern province. Previous experience has shown that if clean cattle are placed there they become very quickly affected with the disease. On December 5, one died from gall-sickness, but, with this exception, all have done very well, and are at this date in perfect health.

This method of inoculation has proved so satisfactory to the farmers themselves that it is being very generally adopted, and the farmers have petitioned the Government to arrange for an inoculating station being placed at Graham's Town, so that clean cattle coming from clean Karroo areas for transmission to the coast may be inoculated previous to entering the infested belt.

April 27.—"Data for the Problem of Evolution in Man. I. A First Study of the Variability and Correlation of the Hand." By Miss M. A. Whiteley, B.Sc., and Karl Pearson, F.R.S.

In a more purely theoretical discussion of the influence of natural selection on the variability and correlation of species, which one of the present writers hopes shortly to publish, a number of theorems are proved which it is desirable to illustrate numerically. But the quantitative measures of the variability and correlation hitherto published are comparatively few in number, especially when, as in the present case, we desire to have their values for a number of local races of the same species. When we have once realised that neither variability nor correlation are constant for local races but are modified in a determinate manner by natural selection and, perhaps, by use, and further that their differences are the key to the problem of how selection has differentiated local races, then the importance of putting on record all the quantitative measures we can possibly ascertain of variability and correlation becomes apparent.

This first study deals only with one character of the hand in one sex and one race. A wider range of material on the skeleton of the hand in another local race is already being dealt with. But while the correlation of the anatomically simple parts of the hand is of very great importance, it does not follow that the complex members of the living hand may not be equally, or even more, significant when we have to deal with fitness for

[1] The conclusions arrived at in that communication (received June 6 1898) were as follows:—

1. The blood of animals, themselves healthy, from a red-water area is dangerous if inoculated into an animal which suffers coincidentally from another disease.

2. That the blood of animals suffering from mild or modified red-water may be safely used to inoculate a healthy animal *subcutaneously*, but is dangerous when injected into a vein.

3. That the subcutaneous inoculation of mild or modified red-water blood conveys a mild form of the disease, and since the blood of such an animal is virulent when injected into a vein in another animal, it is safely to be inferred that the animal suffering from the mild form becomes more or less immunised or "salted."

On these grounds, I would suggest a method of protective inoculation against red-water in the following manner. Having procured a healthy animal from a red-water area or one which is known to have been "salted," inoculate it by injecting 5 c.c. of red-water blood into the jugular vein and 5 c.c. subcutaneously. In cases where the operator is unable to attempt the vein inoculation, I would recommend the subcutaneous inoculation of 5 c.c. in four different sites.

Allow at least twenty-eight days to elapse, and if any degree of illness is recognised, the blood of this animal may be used, after being defibrinated, to inoculate healthy cattle. For such inoculation only 5 c.c. should be injected into small animals, and not more than 10 c.c. into larger.

Seeing, however, that the presence of other maladies renders such a proceeding unsafe, I would recommend that it should only be practised during the autumn or winter, when the veld diseases are, as a rule, in abeyance, and in no case when any epidemic disease is in the near neighbourhood.

the struggle for existence. So far as we have been able to ascertain, although much has been written as to the fitness of the hand for its tasks, no attempt has ever been made to ascertain quantitatively the degree of correlation of its parts.[1] Hence our first object was to get some idea of the correlation of the parts of the hand from an easily measured and in practice important part. Is the hand as highly correlated as the long bones, or as loosely correlated as the parts of the skull, or does it occupy some intermediate position like that of strength to stature? We accordingly selected as an easily measured but still important character the first joint of the fingers. The measurement therefore covers, besides the fleshy parts, the head of the metacarpal bone together with the proximal phalange. It is thus not anatomically simple, but it probably has much importance for the fitness of the hand, and is a measurement which with a little care can be made with considerable accuracy. Our measurements were taken with a small boxwood spanner graduated to 1/10 inch, and provided with a vernier, so that the readings could be nominally made to 1/100 inch. Both the hands of 551 women were measured.

*Relative Size of the Hands.*—We conclude that the first finger joints in the right hand are very sensibly larger than in the left. In every case there is a difference of about 0·02, and this is many times larger than the probable error of the difference, *i.e.* $\sqrt{2} \times 0{\cdot}003$ about.

We might, therefore, assert that the right hand is larger than the left. This conclusion is directly opposed to that of W. Pfitzner; he asserts that there is no quantitative difference between right and left for the simple anatomical parts of the hand skeleton. His own measurements, however, really do show such a sensible difference for the *first* phalange. All then we can say as yet is that the first joint and the first phalange are larger in the right than in the left hand of women. We prefer to state no more sweeping view at present as to other parts of the hand, however strong our private opinion may be.

*Variability of the Hand.*—If we were to judge by *absolute* variations the index and middle fingers of the right hand are less, the ring and little fingers more variable, than those of the left hand. But if we use the more reasonable coefficient of variation, we find that all the first joints for the left hand are more variable than the corresponding joints for the right hand, and this is precisely what we might expect if there be greater adaptation by selection, or by use of the right hand. The greater the selection, the less the variability.

In the left hand the relative order of variability (as measured by the coefficient of variation) is that of the relative size of the fingers; in the right hand this is slightly modified. It would appear that in the right hand the index finger is less variable than the middle finger. The general order of utility of the fingers would appear to be middle finger, index finger, ring finger, little finger, and this exactly agrees with the order of increasing variability in the left hand. The only doubt about this order appears in the relative efficiency and utility of the middle and index fingers, which have a different order of variability in the right hand.

As all our subjects belonged to the educated classes, it is just possible that the great use of the right hand index finger in writing has something to do with this diversity.

*Correlation of the First Finger Joints.*—The conclusions reached are: (1) The hand is a very highly correlated organ, far more highly correlated than the skull, and even somewhat more so than the long bones. We are accustomed to give man precedence in life on account of his brain power, and it might, perhaps, be thought that the brain case would be highly correlated in its parts. Yet what we find is that the skull is extremely individual, its correlations are low, and a man could be readily identified by head measurements, whereas hand measurements would be immensely less safe. In other words, the hand, so far as its dimensions go (we put aside markings), is far closer to a type than the skull.

(2) The parts of the left hand are distinctly more closely correlated than those of the right. The only exception is the correlation of right hand middle and little fingers, which is greater than that of left hand middle and index fingers: but the difference here is considerably less than the probable error of the difference, and the general rule appears to be quite certain. Now this is a most remarkable result; but, again, how is it to be interpreted? Is it a result of selection or a use effect? For the same organ it is a rule that the greater the selection the less the variability and the less the correlation. Exceptions there can be, which will be discussed elsewhere, but this appears to be the general rule. Is the less variability and correlation of the right hand a result of greater selection, or is it after all a result of use? If the latter, we see how hopeless it is to associate constancy of correlation, or even of regression coefficients, with the idea of local races. Indeed the further we enter into the quantitative side of the problem of evolution the more important appears the determination of the influence of growth and use on both variability and correlation. Why is the right hand less variable and less highly correlated than the left? Is the answer the same as to the question: Why is civilised man less variable and less highly correlated than civilised woman?

(3) The order of correlation of the first finger joints is identical for both hands. This order is as follows:—

(*a*) The external fingers have the least correlation and the little finger always less than the index.

(*b*) A finger has always more correlation with a second than with any other finger from which it is separated by the second.

(4) The correlation between corresponding members on both sides is discussed. It is found that again the extreme pairs show least correlation, and the pair of middle fingers higher correlation than the pair of ring fingers.

It is noted that the correlation between corresponding long bones (with the possible exception of that of the radii which is within the probable error of the value for the middle fingers) is greater than that between corresponding parts of the two hands.

The memoir indicates how important it is that the effect of use on both variation and correlation should be determined. It suggests that use may have differentiated in this manner the right from the left hand. But if it has affected variability and correlation here, how far can we look upon these quantities in local races as characteristic of the intensity of selection? The memoir concludes with numerical tables giving the results of the measurements made.

May 4.—"*Onygena equina* (Willd.): a Horn destroying Fungus." By H. Marshall Ward, D.Sc., F.R.S., Professor of Botany in the University of Cambridge.

The genus *Onygena* comprises half a dozen species of fungi, all very imperfectly known, remarkable for their growth on feathers, hair, horn, hoofs, &c., on which their sporocarps appear as drum-stick shaped bodies 5–10 mm. high. The author has recently investigated the life-history of the above species, growing on a cow's horn, and has not only verified what little was known as to its structure, but has been able to cultivate the fungus and trace its course of life, neither of which had been done before, and to supply some details of its action on the horn.

The principal new points concern the development of the sporophores, which arise as domed or club-shaped masses of hyphæ and stand up into the air covered with a glistening white powder. Closer investigation shows this to consist of a hitherto undiscovered form of spores—chlamydospores—developed at the free ends of the up-growing hyphæ. The details of their structure and development are fully described, and their spore nature proved by culture in hanging drops. The germination, growth into mycelia, and peculiar biology of these hitherto unknown spores were followed in detail, and in some cases new crops of chlamydospores obtained direct in the cultures.

The development of the peridium, asci, and ascospores were also followed in detail, and for the first time.

No one had hitherto been able to trace the germination of these ascospores—the only spores previously known in these fungi—and De Bary expressly stated his failure to do it. The author finds that they require digesting in gastric juice. By using artificial gastric juice, and employing glue and other products of hydrolysis of horn, the details of germination and growth into mycelia, capable of infecting horn, were traced step by step under the microscope and fully described.

The author also found that gastric digestion similarly promotes the germination of the chlamydospores, and in both cases has not only traced the germination step by step, but has made measurements of the growth of the mycelium, induced the formation of chlamydospores on the mycelium again, and by

[1] Here, as in other cases, both zoologists and anatomists have since the days of Cuvier, talked a good deal about correlation, but would even to-day be unable to reconstruct, with anything like *quantitative* accuracy, a skeleton from a long bone, a hand from a finger joint, or a skull from a fragment.

transferring vigorous young mycelia to thin shavings of horn has observed the infection of the latter.

It thus becomes evident that the spores of *Onygena* pass through the body of an animal in nature, and, as might be expected from this, extract of the animal's dung also affords a suitable food medium for the fungus. Probably the cattle lick the *Onygena* spores from their own or each other's hides, hoofs, horns, &c., and this may explain why the fungus is so rarely observed on the living animal: it is recorded from such in at least one case however.

Very little is known as to the constitution of horn, and some experiments have been made to try to answer the question—what changes the fungus brings about. The research has bearings on the question of the decomposition of hair, horn, feathers, hoofs, &c., used as manure in agriculture; and may be not without significance in throwing light on the destruction of cuticle, hair, &c., by parasitic fungi.

"The Thermal Expansion of Pure Nickel and Cobalt." By A. E. Tutton, B.Sc. Communicated by Prof. Tilden, D.Sc., F.R.S.

The author has carried out a series of re-determinations of the coefficients of thermal expansion of these two metals with the aid of the interference dilatometer described in a former communication to the Society (*Phil. Trans.*, A, vol. cxci. p. 313; *Roy. Soc. Proc.*, vol. lxiii. p. 208). Since the determinations made by Fizeau in the year 1869, a large amount of additional knowledge has been accumulated with reference to nickel and cobalt, including the discovery of the liquid nickel carbonyl, which places processes of purification in the hands of the chemist of a character so superior to the older methods, as to render it highly desirable that re-determinations of the physical constants of these interesting elements should be carried out with specimens of the metals thus purified. By the kindness of Prof. Tilden, who has prepared such specimens with infinite care for the purposes of the investigation of other physical and chemical characters, the author has been enabled to carry out determinations of the thermal expansion with rectangular blocks varying in thickness from 8 to 13 mm. The blocks were furnished with parallel and truly plane surfaces by the makers of the dilatometer, Messrs. Troughton and Simms. The range of temperature of the observations was from 6° to 121°.

The results of the determinations of the coefficients of linear expansion $\alpha$ are as follows:—

$$\alpha = a + 2bt.$$

For nickel ... $\alpha = 0{\cdot}000\ 012\ 48 + 0{\cdot}000\ 000\ 014\ 8t.$

For cobalt ... $\alpha = 0{\cdot}000\ 012\ 08 + 0{\cdot}000\ 000\ 012\ 8t.$

The coefficients of linear expansion $\alpha$ of pure nickel and cobalt thus exhibit a slight but real difference, the coefficient of nickel being distinctly greater than that of cobalt. This is true with respect to both the constant $a$, the coefficient for 0°, and the increment per degree, $2b$, of the general expression for the coefficient at any temperature $t$, $\alpha = a + 2bt$. The difference is consequently one which augments with the temperature; at 0° it amounts to 3·2 per cent., while at 120°, the upper limit of the temperatures of the observations, it attains 4·5 per cent. Similar rules apply naturally to the cubical coefficients. The metal possessing the slightly lower atomic weight, nickel, is thus found to expand to a greater extent than the metal, cobalt, which is endowed with the higher atomic weight.

"Impact with a Liquid Surface, studied by the aid of Instantaneous Photography. Paper II." By A. M. Worthington, M.A., F.R.S., and R. S. Cole, M.A.

This paper is a continuation of a paper under a similar title, published in the *Philosophical Transactions*, vol. clxxxix., 1897.

It was there shown that, between the splash of a rough and of a polished sphere falling the same distance into water, there is a remarkable difference from the first moment of contact. The causes of this difference are now investigated.

The configuration of the water surface below the general level, when a rough sphere enters, is first studied by instantaneous photography, and the origin is traced of the bubble that follows in the wake of the sphere and of the emergent jet which follows its disappearance. The depression or crater formed round the entering sphere is surprisingly deep. This cavity segments, the lower part following as a bubble in the wake of the sphere, while the upper part fills up by the influx of surrounding water, which gathers velocity as it converges towards the axis of the disturbance, and so produces the upward spirt of the jet.

The actual displacement of the liquid has been studied by letting the sphere descend between two vertical slowly ascending streams of minute bubbles liberated by electrolysis from two pointed electrodes.

The splash of a smooth sphere is traced by gradual transition into that of a rough one as the height of fall is increased. But the course of the disturbance is largely dependent on minute differences in the condition of the surface, and even on its temperature. It was further found that dropping a smooth sphere through a flame, under certain conditions, invariably alters entirely the course of the splash. This action of the flame is proved to be no action of electrical discharge, and reasons are given for attributing it to the burning off of fine dust which has collected on the surface during the fall.

The influence of dust was proved by dusting one side only of a polished sphere, a proceeding which always results in completely changing the character of the splash on the dusted side.

A satisfactory general explanation of all the phenomera is found in the view that with a smooth sphere, cohesion is operative in guiding the advancing edge of the liquid sheath which rises over and closely envelops the sphere. If the surface is not rigid (*e.g.* is dusty), or is rough, then the momentum of the sheath carries it, once for all, away from the surface of the sphere, and the subsequent motion is quite different. The persistence of the remarkable radial ribs or flutings observable in the film that ensheaths a smooth entering sphere is completely explained by the assumption of a viscous drag spreading from the surface of the sphere outwards, and these flutings are always absent from any part of the sheath that has left the sphere. Their presence is thus an indication that there is no finite slip at the solid surface.

Experiments *in vacuo* show that the influence of the air is quite secondary. The similarity of the splash in a liquid with that due to the impact of a steel projectile on an armour-plate is referred to as requiring further investigation.

"The External Features in the Development of *Lepidosiren paradoxa*, Fitz." By J. Graham Kerr. Communicated by A. Sedgwick, F.R.S.

The eggs, averaging between 6·5 and 7 mm. in diameter, are deposited in a burrow at the bottom of the swamp. They are of a pale salmon colour without a trace of dark pigment. Segmentation closely resembles that of *Amia*. Gastrulation begins with the appearance of a row of depressions, or a continuous groove, running round about one-third of the length of the boundary between large and small cells. As this deepens to form the archenteron it shortens up, and the ultimately formed crescentic blastopore is only about a quarter of the length of the original groove. The medullary folds are low and inconspicuous, and meet behind the blastopore, which later becomes the anus. The over-arching of the medullary folds towards one another takes place to a certain extent, but the canal so covered in soon disappears, and the central canal of the nervous system is a secondary excavation. There is no trace externally of a *protostomal* seam running along the floor of the medullary groove. A somewhat tadpole-like larva hatches out, which assumes a remarkably amphibian appearance. This develops on each side four large pinnate external or somatic gills, upon branchial arches I, II, III, and IV. A large cement organ is also present, which during its early stages has the crescentic or U-shape so frequent in the embryos of Anura. Both cement organ and somatic gills are purely larval structures. During the atrophy of the latter they come by differential growth to be situated just over the fore limb, giving a similar condition to that well known in *Protopterus* of a larger growth.

The paper concludes with remarks of a general character upon the phenomena described.

**Linnean Society**, April 20.—Dr. A. Günther, F.R.S., President, in the chair.—Mr. George Murray, F.R.S., exhibited several slides of new *Peridiniaceae*, and gave some account of the method of collection by pumping, which had been found most efficacious with these organisms.—Mr. J. B. Carruthers communicated some observations on the localised nature of the parent characters in hybrid fruits of *Theobroma cacao*, on which some criticism was offered by the Rev. G. Henslow.—Mr. H. H. W. Pearson read a paper on the botany of the Ceylon "patanas," large savannahs in the forests at the same subtropical levels, and with the same climate, though not peculiar to Ceylon. These "patanas" appear to maintain their limits for long periods; but whether they thus exist on account of the

burning of the grass in autumn, or by reason of some peculiarity in the climate, or exposure, is a question on which some difference of opinion has been expressed. A discussion followed, from which it appeared that the author of the paper had not definitely settled the problem.—The Rev. O. Pickard Cambridge, F.R.S., communicated a new list of British and Irish spiders. After reviewing the existing literature on the subject, and the materials which had come to hand since 1881 for a new and revised list of species, the author pointed out that the present paper was not intended merely for the use of authors or collectors interested in local faunas, but to give (with references to primary authorities) the spiders at present known to belong to Great Britain and Ireland, leaving the question of their distribution, abundance, or scarcity to be dealt with at some future time, when the present scanty number of spider-collectors might have increased. At present, large areas of varied natural characters, in some cases whole counties, and many maritime districts, were entirely unexplored, so far as the Arachnology is concerned.—Prof. R. J. Anderson communicated a paper entitled "Imitation as a source of anomalies." Commenting upon the statement made by Profs. Krause and Testut that muscular anomalies are rare in the lower animals, whilst in man they are very common, the author considered it remarkable that no single instance had been authenticated in recent times of a mammal fairly attempting to utter a human voice-sound, although this did not apply to birds. He suggested that in the attempt to imitate, the mental act, or volition, if sustained, might favour a change of a moderate nature, and that such a change might be either progressive or retrogressive.

**Geological Society**, April 26.—W. Whitaker, F.R.S., President, in the chair.—Prof. Emmanuel Kayser, of Marburg, was elected a Foreign Member; and Prof. Franz Lœwinson-Lessing, of Dorpat, and Prof. R. Zeiller, of Paris, were elected Foreign Correspondents of the Society.—On limestone-knolls in the Craven district of Yorkshire and elsewhere, by J. E. Marr, F.R.S. The author begins with a general account of the district, partly founded on the published work of Mr. R. H. Tiddeman, but substantiated by his own observations. The Lower Carboniferous rocks north of the Craven Fault-system differ in character and thickness from those on the south; they exhibit little disturbance on the north, but on the south they are thrown into a series of folds, while it is also on this side that the knobs of limestone called *knoll-reefs* by Mr. Tiddeman occur. The prominent features of the knolls are the crystalline character of the limestone, the horizontality of bedding in the interior of the knolls, the general parallelism of the bedding of the exterior to the contour of the knolls, and the obscurity of the bedding. Fossils, when present, are usually very perfectly preserved and undistorted; breccias are frequently found in the shales bordering the knolls and, much less commonly, in the limestone of a knoll itself. Evidence of movement in the knolls is seen in the lenticular character of the beds of limestone, in visible folded structures, the termination of lenticular beds in hooks against a divisional plane, and in the shales by the presence of a structure undistinguishable from cleavage. Dolomitised and silicified limestones are frequently associated with the knolls, and the perfection of the quartz-crystals in certain examples of the latter variety of rock suggests crystallisation during relief of pressure. The breccias belong to three main types: (1) Fragments of limestone in a matrix of similar material; (2) large nodules of black limestone enwrapped in shales; (3) various limestone-fragments in a fine calcareous paste. Examples of each type are described, and each is explained as resulting from some form of earth-movement. Breccias of similar types are found to be produced out of grit-fragments, and in places the grits are found to be piled together by faulting so as to produce knolls, which somewhat resemble those in the limestone. Dealing with the nature of the movements, the writer argues that the Middle Craven Fault is an overthrust from the north, and that the Limestone Series has undergone differential movements with respect to the hard Lower Palæozoic rocks beneath and the massive Millstone Grit above. The limestones have been squeezed-out from under the synclines, and they have accumulated under the anticlines where the pressure was relieved. In conclusion, a number of examples of knolls are cited from other localities which show similar features, such as the limestones of Keisley, Millom, and near Dalton-in-Furness, some of the Devonian limestones near Torquay, the *Leptaena*-limestone of Dalecarlia, and the Devonian limestone of Koněprus in Bohemia.—The limestone-knolls below Thorpe Fell, between Skipton and Grassington in Craven, by J. R. Dakyns. A band of limestone runs from Cracoe towards the north-east, folded in an anticline and dipping under shales. In several places the top of the limestone is brecciated and the overlying (Bowland) shale contains fragments of limestone. The limestone forms five abrupt conspicuous hills. The rocks in most of these hills are not bedded, and where they are bedded the dip is confusing; both in exposures outside of these and in adits inside, the limestone in some cases is amorphous and without any sign of bedding. The author considers the absence of bedding in the limestone to be a very important feature; for in the country south of the North Craven Fault, though the rock is excessively contorted, its bedding has not been destroyed.—On three species of Lamellibranchs from the Carboniferous Rocks of Great Britain, by Dr. Wheelton Hind. The first part of this paper describes a new species of *Anthracomya* which occurs in the North Staffordshire and Manchester coalfields at horizons higher than that characterised by *A. Phillipsi*. The fossil is found at Etruria, Bradwell, Stoke-on-Trent, and Fallow field. It appears to indicate a special zone of shales and *Spirorbis*-limestone about 300 feet below the Penkhull Sandstone, and to be the only molluscan form known from the zone. A new species of *Carbonicola* is next described, partly from specimens previously supposed to be a gasteropod, a brachiopod, or even a crustacean, and partly from better-preserved specimens obtained from calcareous bands about ten yards above the Bassey Mine Ironstone in North Staffordshire. It appears to be the latest species of this genus known, and to occur in higher beds than any other species. Lastly, a new species of *Ctenodonta* from Penton Linns (Dumfriesshire) is described. It occurs in a marine shale below the highest limestone of the locality, in beds referred to the horizon of the Hurlet Limestone by the officers of the Geological Survey. The bed contains gasteropods, crinoids, cephalopods, &c., with *Productus giganteus*. The species has some resemblance to *C. Halli*, Barrois, found in Spain.

DUBLIN.

**Royal Dublin Society**, March 22.—Prof. D. J. Cunningham, F.R.S., in the chair.—Dr. G. Johnstone Stoney, F.R.S., read a paper entitled "Survey of that part of the range of nature's operations which man is competent to study."—April 19.—Prof. G. F. FitzGerald, F.R.S., in the chair.—Prof. Letts and Mr. R. F. Blake presented the second part of their paper on the carbonic anhydride of the atmosphere, dealing with the amount and causes of variation. The authors discuss (1) the chief natural causes of evolution, (2) those of absorption, and (3) the regulating agencies, and suggest that the chief permanent natural source of evolution—namely, volcanic and subterranean emanations of carbonic anhydride—is kept in check by the absorption of the gas during rock disintegration, and eventually by cretaceous organisms which permanently remove (though of course indirectly) carbonic anhydride from the atmosphere, thus diminishing the supply of carbon necessary for the sphere of organic action. They also suggest that this "degradation" of carbon may finally lead to the extinction of all life on the globe. In the second section of the paper, the question of the temporary fluctuations in the amount of atmospheric carbonic anhydride is considered. These at the lowest estimate at times reach 10 per cent. of the total quantity. Each of the chief natural causes inducing these variations, or supposed to induce them, is discussed and the evidence reviewed; also the *rôle* which ground air plays in the phenomenon is considered. They present with the memoir a very carefully compiled list of the chief original papers which have appeared on the subject, as well as the abstracts of them.—Prof. G. F. FitzGerald communicated a paper, by Mr. D. H. Hall, on the concentration of soap solution on the surface of the liquid. This paper records the results of experiments to determine whether there is any concentration of soap solution in the superficial film of the liquid. The results showed that the soapy matter is so concentrated.—Dr. R. F. Scharff communicated a report on the Crustacea Schizopoda of Ireland, by Messrs. Ernest W. L. Holt and W. I Beaumont, in connection with the Royal Dublin Society's Survey of Fishing Grounds on the West Coast of Ireland. The report includes a complete list of all Schizopods recorded from Irish localities. Two species, *Parerythrops obesa*, G.O.S., and *Mysidella typica*, G.O.S., are added to the British list. A new genus, Dasymysis, is erected for the reception of *Mysis longicornis*, M.-Edw., Czerniavsky's genus

Acanthomysis having been defined in such a manner as to exclude the type. Reasons are given for doubting the specific validity of *Macromysis neglecta*, G.O.S., and the characters of *Erythrops serrata*, G.O.S., are re-defined.—Prof. J. Joly, F.R.S., communicated a paper, by Mr. Kingsley D. Doyle, on the Rio del Fuerte of Western Mexico and its tributaries. The paper is a valuable series of notes, arranged topographically, concerning the geology, physical geography, and meteorology of the district explored.

### EDINBURGH.

**Royal Society**, May 1.—Prof. Copeland in the chair.—Lord Kelvin's paper on the application of force within a limited space required to produce spherical solitary waves, or trains of waves, of both or either species, equivoluminal and irrotational, in an elastic solid, was briefly described. It will be found in the May number of the *Philosophical Magazine*.—Dr. Alexander Galt, in a further communication on the heat of combination of pairs of solid metals, mentioned that practically there was no heat of combination in copper-silver alloys, but that heat of combination was found in most of the copper-zinc alloys. The maximum was obtained when the metals, considered as bivalent elements, were in proportions approximating to their chemical combining proportions—about 49·8 per cent. copper. With diminishing percentage of copper, the heat of combination gradually diminished, becoming zero when there was about 30 per cent. of copper. With still smaller proportion of copper, *the heat of combination became negative*.—Dr. C. Wace Carlier read a paper on changes that occur in some cells of the newt's stomach during digestion. As soon as food is swallowed, secretion commences near the œsophagus and sweeps in a slow wave along the whole organ, reaching the pyloric glands in one to two hours. Each cell is exhausted in about four hours, following which there is a period of rest and recuperation lasting other four hours. During exhaustion, the nuclei undergo changes in size, losing chromatin, which is used up in the production of prozymogen. The nucleoli are effete products, derived mainly from the chromatin, and are extruded from the nuclei. The prozymogen passes into the cytoplasm and unites with an albuminous material to form zymogen, which is readily converted into zymin by the action of weak acids. Repair of chromatin begins by the passage into it of substances from the cytoplasm. These become gradually broken up, the nuclear radicle passing to the chromatin, and the albuminous material to the nucleoli as effete matter. When (but not until) this process is complete, the cell is again ready to recommence secretion if called upon to do so. Oxyutic cells divide by mytosis, and, in process of division, secrete zymin and form prozymogen from the chromatin just as cells not in process of division do.—In a paper on the leakage of electricity from charged bodies at moderate temperatures, Prof. J. C. Beattie described in detail results of experiments with zinc and iron plates coated with various substances. Under any given condition the rate of leakage of charge from the insulated plate was determined (1) at ordinary temperatures; (2) at temperatures of 150°–300° C. With the plate by itself or covered by certain materials there was no change in the rate of leakage as the temperature was raised. With certain coatings, however, there was greatly increased leakage at the higher temperatures. This was the case, for example, when zinc was coated with potassium bichromate and iodine; and when iron was coated with potassium permanganate or with potassium acetate.—Professor Tait, in a note on the linear and vector function, showed that if $\phi$ represented a strain with three real roots, so also did $\psi \phi \psi^{-1}$ where $\psi$ was any linear and vector function whatever. As formerly shown, $\phi$ may be written as the product, $\omega\ \pi$, of two pure strains. Hence $\psi \phi \psi^{-1} = \psi \omega \psi'.\ \psi'^{-1} \pi \psi^{-1}$, in which each triple compound is obviously self-conjugate, and hence $\psi \phi \psi^{-1}$ can also be expressed as the product of two pure strains.

### PARIS.

**Academy of Sciences**, May 15.—M. van Tieghem in the chair.—M. Prillieux took his place as a member of the Botanical Section.—Experimental application of decimal circular divisions in practical navigation, by M. E. Guyou. An account of some experiments to be undertaken on the extension of the decimal system to the instruments and tables employed in navigation. The advantages of the system and the difficulties attending its introduction are discussed.—Effects of auto-excitation of the heart by the extra-current of the electromagnetic indicator used in recording cardiac valvular movements, by M. A. Chauveau. Further experiments are described, showing the extreme sensitiveness to induced currents of the heart of the horse.—New elements of the orbit of the planet EL, by MM. Lubrano and Maitre.—Representation of uniform branches of analytic functions, by M. G. Mittag-Leffler.—Calculation of formulæ containing arbitrary functions, by M. Jules Beudon.—Want of generality in the theory of the fictitious polarisation of dielectrics, by M. H. Pellat. The theory in question is incapable of explaining the forces produced when a dielectric, originally non-electrified, is placed in an electric field.—Influence of the source of electricity in the use of Michelson's vacuum tubes, by MM. A. Perot and Ch. Fabry. The best results, as regards the production of phenomena of interference, are obtained by the use of a continuous current with an electromotive force of at least 700 or 800 volts.—On the electrolytic luminous sheath, by M. E. Lagrange.—Substitution of magnetic for mechanical action in coherers, by M. Th. Tommasina. The chains formed by the metallic particles are broken by the action of an electromagnet.—Transmission of light through turbid media, by M. P. Compan. It is shown experimentally that the nature of the light transmitted by turbid media is dependent on the dimensions of the suspended particles.—Calculation of the compressibility of a gaseous mixture from the compressibility of its components, by M. Daniel Berthelot. The method of calculation is based on Van der Waals' formula, and the theoretical numbers show a satisfactory agreement with the experimental values.—On the preparation and properties of tungsten pentabromide, by M. Ed. Defacqz. A new method for the preparation of tungsten pentabromide is described, based on the action of dry hydrogen bromide on the hexachloride at about 300° C. The satisfactory yield obtained by this process enabled the properties of the compound to be studied more completely than has hitherto been possible.—On the mixed halogen salts of lead, by M. V. Thomas. The author describes a bromochloride of the formula $3PbCl_2, PbBr_2$, obtained by mixing solutions of lead chloride and potassium bromide, a bromochloride PbBrCl formed by the action of bromine on the corresponding chloriodide which has previously been described, and a bromoiodide of the formula $3PbBr_2, PbI_2$. A bromoiodide having the composition PbBrI also appears to exist.—Separation and estimation of traces of bromine in the presence of a large excess of chlorides, by M. H. Baubigny. The bromine is separated from the bulk of the chlorine by distilling the salts with potassium permanganate and a limited quantity of hydrochloric acid. Less than 0·0005 gramme of bromine may thus be detected and estimated in the presence of 10 grammes of sodium chloride.—On the activity of manganese in relation to the phosphorescence of strontium sulphide, by M. José Rodriguez Mourelo. The influence of manganese carbonate, in rendering strontium sulphide phosphorescent, is similar to that of bismuth subnitrate as described in previous communications.—On pectins, by M. Em. Bourquelot. Five varieties of pectin, obtained from different plants, have now been examined. All are dextrorotatory to a greater or less extent, and their solutions are coagulated by pectase. On hydrolysis with dilute sulphuric acid arabinose is obtained, whilst mucic acid is formed on oxidation with nitric acid.—Action of toluylene-diamine on the red corpuscles of the blood, by MM. L. Lapicque and A. Vast. Experiments tend to show that the toxic action of toluylene-diamine is due not so much to a specific destruction of the corpuscles as to an alteration of the latter which facilitates their destruction by the hæmatolytic organs, and especially by the liver.—On the galvanotropism of ciliated infusoria, by M. Henri Mouton. The phenomenon of galvanotropism appears to be due to the direct action of the current, and not to the chemiotropic action of the products of electrolysis.—On the forms of conservation and reproduction of "black rot," by M. Joseph Perraud. It follows, from the author's observations, that burying the affected parts of the plant is of no avail unless the soil is subsequently left undisturbed.—*Botrytis cinerea* and the "Toile" disease, by M. J. Beauverie. The destructive action of the parasite is favoured by a high temperature, a moderately nutritive substratum, and a confined atmosphere saturated with aqueous vapour.—On the germination of *Neottia nidus-avis*, by M. Noel Bernard.—On a *tachylite* from the bed of the North Atlantic Ocean, by M. P. Termier.

AMSTERDAM.

Royal Academy of Sciences, March 25.—Prof. van de Sande Bakhuyzen in the chair. —Prof. Zaayer reported, both on behalf of Prof. Fockema Andreae and himself, upon a letter from the Minister of the Interior, concerning the question addressed by the Belgian Ambassador to the Dutch Government with respect to prize essays.—Prof. Pekelharing reported, both on behalf of Prof. Winkler and himself, on the paper of Dr. G. C. van Walsem, entitled "An attempt at a systematical method of the normal and pathological microscopo-anatomical and anthropological inquiry into the central nervous system." This paper will be published in the Academy's *Transactions*.—Prof. J. C. Kluyver, on reducible hyperelliptic integrals. The paper deals with the algebraic conditions to be satisfied by hyperelliptic equations, when it is possible by a theta transformation of the $r$-order to arrive at a period matrix of which the constituents, all but the first, are equal to zero. Particularly the cases $p = 2, 3$, $r = 2, 3$ are considered. An expression of the invariant relation between the branch places is given for the case $p = 2$, $r = 3$, also a proof for the special form of the reducible integral, mentioned by Prof. Burnside (*Proc. Lond. Math. Soc.*, vol. xxiii.)—Prof. Winkler, on inquiries, made by Mr. Wiardi Beckman and himself, into the influence that expiration undergoes through faradic irritation of certain sensible and sensory nerves.—Mr. Hamburger, on the influence of salt solutions on the volume of animal cells (second communication).—Prof. Van der Waals, on an anomaly in the course of the plait-point curve in the case of a mixture of anomalous substances. All these communications will be inserted in the *Proceedings*.—The following papers were also presented for publication in the *Proceedings*: Prof. Van der Waals, on volume and pressure contraction (iii.); and on behalf of Prof. L. Boltzmann, foreign member of the Academy, on the characteristic equation of Van der Waals.—Prof. Kamerlingh Onnes, on behalf of Dr. E. van Everdingen, jun., on the galvanomagnetic and thermomagnetic phenomena in bismuth (second communication).—Prof. Bakhuis Roozeboom, on behalf of Dr. Ernst Cohen, on electrical reaction velocity.

April 22.—Prof. Van de Sande Bakhuyzen in the chair.—Prof. Bakhuis Roozeboom communicated the first experiments, made for the confirmation of his theoretical views, concerning the melting points of optical isomers. These views were confirmed in the case of mixtures, both of racemic and dextro-dimethylethereal salts of tartaric acid and of the same derivatives of diacetyltartaric acid. In the first system, the inactive ester had a higher melting point than the active one; in the second system, it was just the opposite.—Prof. Kamerlingh Onnes presented, on behalf of Dr. E. van Everdingen, jun., a communication concerning the galvanomagnetic and thermomagnetic phenomena in bismuth (a continuation of the second communication).—Prof. Van der Waals presented a paper on the deduction of the phase equation, being a controversy with Prof. Boltzmann.

## DIARY OF SOCIETIES.

*THURSDAY*, MAY 25.

ROYAL INSTITUTION, at 3.—Water Weeds: Prof. L. C. Miall, F.R.S.

*FRIDAY*, MAY 26.

ROYAL INSTITUTION, at 9.—Climbs and Explorations in the Andes: Sir W. Martin Conway.

PHYSICAL SOCIETY, at 5.—On the Thermal Properties of Normal Pentane, Part 2: Prof. S. Young and Mr. Rose-Innes.—On the Distribution of Magnetic Induction in a Long Iron Bar: C. G. Lamb.

AERONAUTICAL SOCIETY, at 8.—Exhibition of Models: Lawrence Hargrave and Dr. Barton.

*MONDAY*, MAY 29.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30—Explorations in Patagonia and the Eastern Andes: Dr. Francisco Moreno.

*TUESDAY*, MAY 30.

ROYAL INSTITUTION, at 3.—Recent Advances in Geology: Prof. W. J. Sollas, F.R.S.

SOCIETY OF ARTS, at 8.—The Revival of Tradesmen's Signs: J. Starkie Gardner.

ANTHROPOLOGICAL INSTITUTE, at 8.30.—On the Beginnings of Currency: Lieut.-Colonel R. C. Temple.

*THURSDAY*, JUNE 1

ROYAL SOCIETY, at 4.—Election of Fellows. —At 4.30 —*Probable Papers*: The Parent-Rock of the Diamond in South Africa: Prof. T. G. Bonney, F.R.S.—Results of Experiments in Telegony: Prof. Ewart, F.R.S.

ROYAL INSTITUTION, at 3.—Water Weeds: Prof. L. C. Miall, F.R.S.

LINNEAN SOCIETY, at 8.—On the High Level Plants of the Andes as illustrated by the Collections of Sir W. Martin Conway, Mr. Edward Whymper, and others: W. Botting Hemsley, F.R.S.—On some Australasian Collembola: Sir John Lubbock, Bart., F.R.S.

SOCIETY OF ARTS, at 4.30.—The Port of Calcutta: Sir Charles Cecil Stevens, K.C.S.I.

CHEMICAL SOCIETY, at 8.—The Hydrosulphides, Sulphides, and Polysulphides of Potassium and Sodium: W. Popplewell Bloxam.—On the Relative Efficiency of various Forms of Still-head for Fractional Distillation: Dr. Sydney Young, F.R.S.—The Salts of Dimethylpyrone, and the Tetravalence of Oxygen: Dr. J. N. Collie, F.R.S., and Thomas Tickle.

*SATURDAY*, JUNE 3.

ROYAL INSTITUTION, at 3.—The Music of India and the East, and its Influence on the Music of Europe (with Musical Illustrations): Edgar F. Jacques.

## BOOKS, PAMPHLETS, and SERIALS RECEIVED.

BOOKS.—Sewage-Analysis: J. A. Wanklyn and W. J. Cooper (Paul).—Anleitung zur Darstellung Chemischer Präparate: Prof. H. Erdmann, Zweite Auflage (Frankfurt a.M., Bechhold).—Einleitung in die Vergleichende Gehirnphysiologie und Vergleichende Psychologie: Dr J. Loeb (Leipzig, Barth).—Accounts of the Trade carried by Rail and River in India, 1897–98, &c. (Calcutta).—Flora of Kent: F. J. Hanbury and E. S. Marshall (Hanbury).—A Treatise on Practical Chemistry, &c.: Dr. F. Clowes, 7th edition (Churchill).—Die Entstehung des Lebens: Dr. L. Zehnder, 1 Teil (Freiburg i.B., Mohr).—Cries and Call Notes of Wild Birds: C. A. Witchell (Gill).—Man, Past and Present: A. H. Keane (Cambridge University Press).—A Select Bibliography of Chemistry: H. C. Bolton, 1st Supplement (Washington).—Wetterprognosen und Wetterberichte des xv. und xvi. Jahrhunderts (Berlin, Asher).

PAMPHLETS.—Hey for the Holidays! (R. E. Taylor).—Sull' Impiego del Microsismografo, &c. (Venezia, Ferrari).—History and Present Status of Instruction in Cooking in the Public Schools of New York City (Washington).—The Slide-Valve Simply Explained: W. J. Tennant (Dawbarn).

SERIALS.—Zeitschrift für Wissenschaftliche Zoologie, lxv. Bd., 4 Heft (Leipzig).—Die Meteorologie der Sonne und das Wetter im Jahre 1889, &c.: Prof. K. W. Zenger (Prag, Rivnáč).—Knowledge, May (Witherby).—Journal of the Chemical Society, Supplementary Number (Gurney).—Memoirs and Proceedings of the Manchester Literary and Philosophical Society, Vol. 43, Part 1 (Manchester).—Atlantic Monthly, May (Gay).—Atti della Fondazione Scientifica Cagnola della sua Istituzione in Poi, 1896–97, 1897–98 (Milano).—Zoologist, May (West).—Physical Society of London Proceedings, May (Taylor).—Morphologisches Jahrbuch, 27 Bd. 2 Heft (Leipzig).—Journal of the Franklin Institute, May (Philadelphia)—Popular Astronomy, May (Northfield, Minn.).—Psychological Review, Monograph Supplement, Vol. 2, No. 5 (Macmillan).—American Anthropologist, April (Putnam).—Astrophysical Journal, April (Chicago).—Proceedings and Transactions of the Nova Scotian Institute of Science, Vol. ix. Part 4 (Halifax, N.S.).—Proceedings of the Academy of Natural Sciences, 1898, September–December (Philadelphia).—Annals of the Astronomical Observatory of Harvard College, Vol. xxxix. ## EVOLUTION WITHOUT SELECTION.

*Die Farbenevolution bei den Pieriden.* Von M. C. Piepers. "Tijdschrift der Nederlandsche Dierkundige Vereenignig; 2. Deel v." Pp. 70–289. (Leiden, 1898.)

THE fact is becoming more and more widely recognised that the colours of animals, and especially of insects, afford excellent material for the investigation of dark places in the theory of evolution. As was long ago pointed out by Bates, and reiterated with increased emphasis by Wallace, the history of the modification of species is displayed to view on the wings of butterflies in a manner that is peculiarly legible and strikingly complete. There is, therefore, every justification for those students of evolution who, like Weismann, Eimer, Meldola, Poulton, Bateson, and several others, have devoted much attention to the colour patterns of lepidopterous insects, and have endeavoured with more or less success to use the facts made available by such detailed examination in the elucidation of the laws which govern the origin and development of species.

The pamphlet named at the head of this article is the work of an author whose credentials entitle him at least to an attentive hearing. He has resided for nearly thirty years in the Malay Archipelago—chiefly in the island of Java; during the whole of which time, as he tells us, he has studied the entomology of that region, and has in particular continued to search for explanations of the various phenomena presented by the colours of its lepidopterous fauna. It might be expected, then, that he would be able to bring forward a mass of valuable material derived from such observations and experiments as can best be carried out amid the natural surroundings of tropical species, and would thus be in a position to afford real help towards the solution of questions like those of the value in the struggle for existence of mimetic or of warning colours, the importance of sexual selection and the protective significance of seasonal modifications. So far from this being the case, however, it must unfortunately be stated that he has done little or nothing to increase our knowledge in any of these or similar directions.

The cause of his failure is not far to seek. Being, as he informs his readers, in most respects a follower of Eimer, though disagreeing with his master on certain points of detail, he looks for an explanation of organic evolution in the direction of "laws of growth," uncontrolled by any process of selection, but working out the transformation of species under the influence of external conditions which act upon organisms of varying degrees of susceptibility. The essence of his contention is the non-recognition of selection in any form as a factor in evolution, and he is apparently so sure of his position on *à priori* grounds, that he has not thought it worth while to keep the selection hypothesis in view even as a provisional basis for observation and experiment. This, the πρῶτον ψεῦδος of his position, has had a most disastrous effect upon his work, both as an observer and as a reasoner. It cannot be said that he has any new arguments of weight to bring forward; the main part of his treatise is taken up with a laborious attempt to show that the course of colour-evolution in the Pierids (or "white" butterflies) has followed, and is following, a definite succession of stages, which continually occur in the same order. Starting from an original red, the process of colour-change in the Pierids, according to Piepers, is always tending to reach a final stage of white, which may be attained either by means of a gradual paling through orange and yellow, or through an intermediate condition of black. This inevitable tendency, arising from an internal impulse towards change in a definite direction, taken in conjunction with external influences which act chiefly by way of accelerating or retarding the process of change, and in relation with individual differences of susceptibility to stimulus, he believes to have been sufficient for the production of the assemblage of diverse forms which constitute the Pierid sub-family as at present existing.

It is no doubt true that, speaking generally, there has been a fairly uniform tendency throughout this group of butterflies towards the replacement of an original dark by a white pigment. But this was not reserved for Piepers to discover, inasmuch as the view in question has been long ago advanced and supported by much more detailed evidence than that brought forward in the present treatise. Moreover, cases have been pointed out where, in consequence of mimetic adaptation or from other causes, the more usual process of change has been reversed or modified—a fact not noticed by Piepers, and not very favourable to his general view. But acquaintance with the work of his predecessors scarcely appears to be a strong point with the author, who frequently either ignores altogether, or dismisses in a curt sentence or two, results of other observers which certainly demand and deserve a careful comparison with his own. The part of his theory for which he really is entitled to claim originality, viz. that the primitive colour of Pierids was a uniform shade of red, seems to rest on extremely slender evidence. To any one who will take a comprehensive view of the whole sub-family, the conclusion from which Piepers does not shrink, viz. that the male of *Appias* (*Tachyris*) *zarinda* most nearly represents in coloration the earliest form of Pierid, will appear to savour of the *reductio ad absurdum*. Without going into the kind of detail which would here be out of place, we may safely assert that there is abundant evidence in favour of the contrary view; and that in many cases, at all events, as in the genera *Mylothris* and *Dismorphia*, there is every reason to attribute the presence of much of the red or orange coloration rather to increased specialisation for a distinct purpose, viz. that of mimicry, than to reversion or survival. Hopkins's researches on Pierine pigments are not unknown to Piepers, but the latter, perhaps wisely, refrains from attempting to reconcile them with his own conclusions.

This brings us to what appears to us to be a serious offence on the part of the author against good taste and good manners in scientific controversy. Nothing but gratitude is due to him for the facts that he has recorded from his own experience; most readers, indeed, will only wish that he had given us more of them. Nor can any one fairly complain of his absolute denial of the modifying influence of selection, even though he thereby puts him-

self in opposition to Darwin, Wallace, Fritz Müller, Weismann, and most of those whose labours have contributed to the establishment of the theory of evolution. But in speaking of views which he does not himself hold, he repeatedly allows himself to use language which is highly unbecoming in a scientific man. This is especially noticeable in his remarks on the subject of mimicry. We are of course prepared to find that he does not believe in it, but it might be thought that a view which commended itself to Bates, Wallace, F. Müller, and Trimen, to say nothing of Darwin himself, was at least deserving of respectful treatment. M. Piepers does not think so, and his language on the subject is so uncontrolled as to suggest doubts whether, in spite of his training as a jurist, he can be considered a fair and competent examiner of evidence. It is easy enough to throw about words like "Aberglaube" and "Humbuglehre" in reference to the views of other workers, and to suggest that opponents are "mentally abnormal"; but such expressions recall the methods of the advocate rather than of the judge, and they render their employer liable to severe retaliation, did any one care to administer it.

A conspicuous instance of this want of restraint occurs in the note on p. 279; where the author altogether overreaches himself in his denunciation of Schröder. It is not our business to correct his literary blunders, but we cannot help thinking that the original utterer of the famous line "homo sum; humani nil a me alienum puto" (misquoted, by the way) would be somewhat surprised to see himself referred to as "the old philosopher." This, however, may pass; more open to question is the wisdom of introducing the quotation at all. M. Piepers seems to think that the upholders of mimicry will be "angry" at his strictures. They are more likely to be amused, and perhaps a little saddened, for there is always an element of pathos in resistance to the inevitable.

Protective resemblance, in relation to selection, fares no better with the author than mimicry itself. Thayer's demonstration of the protective value of the pale underside of birds and mammals is convincing enough for most minds; Piepers simply dismisses it with the remark that he cannot admit it in the case of insects. One is tempted to ask him what he expected in the case of insects, but this dictum is a not unfair specimen of his critical method generally. It is difficult to answer a disputant who holds (p. 250) that the resemblance to forms of vegetation shown by the underside of *Euchloe cardamines* and even of *Kallima paralecta* is accidental. The somewhat unseemly comparison on the same page is perhaps meant for a joke. If so, it says very little for the author's humour; if not, it says even less for his logic.

The treatment of seasonal forms affords another instance of his curious reluctance to accept the plain and obvious explanation of certain facts, if that explanation involves a recognition of the principle of selection. Some of his remarks on the varying forms of Malayan butterflies have all the interest and importance which naturally belong to the personal observations of a good field naturalist, but it is strange to find him still advancing theories of the direct influence of local conditions which were long ago discarded by Wallace. The truth which underlies his statements is probably this—that polymorphism gives an opportunity to selection, under which influence it may become limited by locality and season. In his discussion of the permanent or variable whiteness of certain animals, he cannot of course shut his eyes to the fact that the same visual effect of whiteness is produced in different cases by different means. He remarks in a somewhat puzzled way that there is nevertheless evidently some connection between the whiteness caused by a white pigment (so-called) and that due to scattered reflection. Of course there is, or may be, such a connection; but the obvious key to the mystery, viz. selective adaptation, is not even noticed by him.

It is really pitiful to witness the straits to which those evolutionists are reduced who desert the firm and clear lines laid down by Darwin. Towards the end of his treatise M. Piepers makes a certain appeal for the indulgence due to an amateur. We are inclined to admit his claim, and to judge him leniently on that account. Courage and candour he does not lack, and it is deplorable that having tasted the "Pierian spring," he has not taken a deeper draught of its waters. A little more reading would have shown him that many of his discoveries had been already made, and that most of his difficulties had been answered by anticipation.

F. A. D.

## *PROFESSOR TAIT'S COLLECTED PAPERS.*

*Scientific Papers.* By Peter Guthrie Tait, M.A., Sec.R.S.E., &c. Vol. i. Pp. xiv + 498. (Cambridge University Press, 1898.)

THE Cambridge Press has already laid mathematical and physical workers under deep obligations by its editions of Maxwell, Stokes, Thomson, and Cayley. It now proposes considerably to extend these obligations, and as an instalment of their fresh enterprises we have here the first volume of the collected papers of Prof. Tait. This reprint appeals to readers of widely different interests, and will be welcomed by all, not only on account of the highly specialised investigations of various kinds which it contains, but also as a monument to a writer to whom science owes a great deal.

It would be out of place, even if the reviewer were competent, to attempt any detailed examination of the papers here presented. They have been before the world for many years, and their value and originality have not been contested. A rapid sketch of the contents may, however, be given. A large proportion of the book is taken up with the quaternion investigations in which Prof. Tait first made his mark, and to which he has returned from time to time with undiminished enthusiasm. The precise scope and value of the quaternion method are questions on which opinions have greatly differed, and the number of mathematicians otherwise eminent who could be reckoned as fully concurring in Prof. Tait's views on these points is probably very limited. In this country there has been a certain natural diffidence, and perhaps a little want of courage, which have hindered the free expression of opinion; but on the continent the assertion has been made again and again that the subject has in some respects been unfortunate in its expositors, and that the elements of undoubted value in the theory have been unduly discredited by the somewhat excessive claims made on its behalf. It is possible to sympathise

with this view, and yet to attach very high importance to the investigations now in evidence. They are concerned mainly with the processes of differentiation and integration as applied to quaternions, and especially with the properties of Hamilton's operator

$$i\frac{d}{dx}+j\frac{d}{dy}+k\frac{d}{dz},$$

a branch of the subject which (as is well known) has exercised a great fascination on many distinguished cultivators of mathematical physics, from Maxwell downwards. That Prof. Tait's papers remain the primary, and indeed almost the sole, authority on such matters, is ample warrant for the present republication. For the rest, a few items gathered from the titles, such as Fresnel's Wave-Surface, the Theory of Electrodynamics, the Theory of Strain, the Dynamics of Rotation, Green's Theorem, Isothermal Surfaces, and Minding's Theorem, will indicate the variety and importance of the subjects which Prof. Tait has sought to bring within the range of this ambitious calculus.

Passing from this group, we have to notice an elaborate investigation on "Knots," suggested originally by Thomson's theory of vortex-atoms. It deals with a branch of the Geometry of Position which few mathematicians (and those only of the ablest) have ventured to touch; and although the presentation disclaims any finality, there can be no doubt that Prof. Tait's investigations must be accounted a solid and valuable, as they are an interesting contribution to the subject.

It would be ungrateful to pass over a number of minor papers which are specially characteristic of Prof. Tait in respect of the symmetry and elegance of the mathematical treatment, or of the manner in which new light is thrown on well-worn topics. Of these the papers on Hamilton's Characteristic Function, and on the Hodograph, may be cited as specimens. In this latter we find the now well-known representation of a small oscillation in a resisting medium as the projection of motion in an equiangular spiral, as well as several other results or modes of proof which have long become common property. It is pleasant to be reminded of their real source.

A very attractive topic is treated alike with originality and elegance in the paper on "Mirage."

There remain the experimental papers. Of these it may be sufficient to here say that those on Thermo-Electricity have long ranked as classics; and that the paper on the pressure-errors of the *Challenger* thermometers is an interesting record of a laborious investigation undertaken to decide a very important practical question.

Some readers may perhaps be disappointed to find that one side of Prof. Tait's activity is not represented in these pages. He has in his time been engaged in many keen controversies, in which he has displayed the qualities of a "first-class fighting man." One cannot but feel, therefore, great admiration for the restraint he has shown in omitting all traces of such incidents from the present record of his work. There is, in fact, only one paper which one would willingly have spared, and that for quite other reasons. The lecture on "Force," with its insistence on what after all are verbal questions, is surely out of place in the present collection. The readers who are capable of following the *technique* of quaternions, or the intricacies of amphicheiral knots, do not need to be lectured on the looseness of newspaper language; whilst the grave discussion as to whether force or energy has the greater title to rank as a "thing" will hardly excite in them any other feeling than the amusement which (one suspects) may have been the real object of the whole discourse.

The printing and general appearance of the volume are beyond praise. One might, indeed, protest that the *format* is a little *too* luxurious. Many persons hold to the view that the octavo form adopted in the cases of Stokes and Thomson is far more handy and convenient for real work than the more imposing quarto. In the case of Cayley, the larger form was perhaps required by the nature of the subject-matter, with its long algebraical formulæ; but there is little in the present collection which could not with a little ingenuity have been accommodated in the smaller page. But such criticisms are, after all, somewhat ungracious. We conclude by thanking the University and Prof. Tait for this very acceptable volume, which we trust to see speedily followed by a second. And we venture to suggest to the University Press that an additional and welcome element of interest would be imparted to these reprints if they could be adorned with portraits of the authors, even when these are happily still amongst us. HORACE LAMB.

## OUR BOOK SHELF.

*Elementary Physiology.* By Benjamin Moore, M.A. With 125 Illustrations. Pp. vi + 295. (London: Longmans, Green, and Co., 1899.)

THIS book contrasts favourably with most others of its class. A small treatise of three hundred pages on elementary physiology can scarcely avoid being superficial, and, from the students' point of view, inadequate; but to these inevitable shortcomings there are too often added, in books of the kind, the quite gratuitous defects of inaccuracy in statement and failure to keep up with the advance of knowledge. From faults of the latter description the work before us is practically free, and it may be commended with confidence to the junior student, who, as the author says, "is often plunged into a mass of detail, and gets so involved in this, that he loses sight of the main outstanding features of the subject." Most teachers of physiology have probably had experience among their pupils of the mental condition here referred to. Lucid and concise in statement, Mr. Moore's book manages to convey a large amount of accurate information in very small compass. It bears ample evidence of being no mere literary compilation, but the production of a genuine worker in physiology, whose mode of treatment is often striking and original. As might be expected from the author, the book is especially strong in such matters as digestion, absorption and metabolism.

The volume is in most respects so meritorious that it seems ungracious to call attention to its blemishes. These are, as a rule, not serious. It would be unfair to find fault with a book of this kind for being dogmatic; it is plainly not a fitting place for the discussion of controverted questions. The statement, however, on p. 14, with respect to the relations of cartilage and bone is distinctly misleading. But with few exceptions the points that call for criticism concern the form of the book rather than its matter. Thus, the author is occasionally guilty of an awkwardness or inelegance of language that might easily have been avoided, and we cannot say that we approve of such colloquialisms as "harking back again to our simple type," or "that bigger supply of

blood to the cells which is required." In many places the sense is seriously interfered with by faulty punctuation, and we note a rather plentiful crop of misprints, especially towards the end of the book. Such are "centre nervous system," "tircuspid," "vertebræ," (for "vertebrata"), "cauda equinæ," "straining" (for "staining"), "Weber-Feehner law," "fenestra rotundis," (several times repeated), "scala tampani," "selerotic," "viteous humour." Nor do we care for the form "oculimotor." It is to be hoped that a future edition will be more carefully revised. The author has been fortunate in securing the use of the well-known and admirable figures from Quain's "Anatomy" and Schäfer's "Essentials of Histology." They add materially to the value of the work.

*The Dawn of Reason.* By James Weir, jun., M.D. Pp. xiii + 234. (New York: The Macmillan Company, London: Macmillan and Co., Ltd., 1899.)

THIS book on the mental processes of animals is the fruit of much original observation, and in many cases this observation has been supplemented by experiment; but, unfortunately, all the author's results are vitiated by his uncritical and biased attitude in favour of an extreme view of the mental life of animals, and there are few of his facts which the comparative psychologist would be justified in using without ample corroboration by other observers. Instinct is regarded as the great bane of psychology, and it almost seems as if the author believed it to be a special invention of those whom he calls "creationists." He poses as an ardent evolutionist, but is so blind to the most elementary principles of the evolution of mind that when a water-louse frightens some rhizopods, he can only conclude either that the latter have eyes and ears so small that lenses of the highest power cannot make them visible, or that these creatures are the possessors of senses utterly unknown to and incapable of being appreciated by man. He makes observations on spiders which show that they are differently affected by loud and soft vibrations of an organ—observations which do not even demonstrate the existence of hearing—and concludes that these animals have attained a very high degree of æsthetic musical discrimination. He has also seen a spider "intentionally beautifying" its web with flakes of logwood, and he has watched rhizopods employing their time in "simple amusement" resembling a game of tag. Nevertheless, among these extravagances, one meets with observations which would be of distinct value and interest if one had confidence in the observer.

*The Arithmetic of Chemistry.* By John Waddell, B.Sc. D.Sc. Pp. viii + 133. (New York: The Macmillan Company. London: Macmillan and Co., Ltd., 1899.)

THE volume does not differ essentially from other books on chemical arithmetic. Every teacher has his own method of presenting an arithmetical problem, which he often feels impelled to share with others. The author's methods seem thoroughly sound and logical, and no exception can be taken to them. There is a good deal to be said, too, for the plan of treating the calculations on a purely experimental basis independently of theories; but it is not always advisable to hold to it too rigidly. A good illustration is offered by the following example.

The author begins by showing that the combining weight of oxygen taken as 8 is thoroughly satisfactory, not only in its relation to hydrogen (1) in water, but to carbon (6) in its two oxides. It then becomes necessary to explain that this number for oxygen does not fulfil the expectations which it first raised, and that the formula for water HO(9) must be discarded in favour of $H_2O(18)$. "It is found that while by electrolysis of water all of the hydrogen that is in the water is set free as a gas, and $\frac{1}{9}$ of the water decomposed is hydrogen; on the other hand, when sodium acts on water, only one-half as much hydrogen is set free, that is $\frac{1}{18}$ of the weight of water acted upon." It is questionable whether this explanation would carry conviction to the beginner. A plain dogmatic statement would surely serve the purpose better, until the student had advanced to a stage when he could grasp the whole question involved. The author has collected together an excellent set of examples from a variety of sources, which should be useful to teachers in elementary classes. J. B. C.

*The Flora of Cheshire.* By the late Lord de Tabley (Hon. J. Byrne Leicester Warren), edited by Spencer Moore; with a Biographical Notice of the Author by Sir Mountstuart Grant Duff. Pp. cxiv + 399, with a portrait of the author and a map of the county. (London: Longmans, Green, and Co., 1899.)

THE manuscript of this "Flora," we are told, was completed a quarter of a century ago. Those who knew the sensitive, retiring disposition of the late Lord de Tabley will not be surprised that he laid it aside as not ready for press; nor will they be surprised at the excellence of what was done. There is little beyond an enumeration of the plants of the county, but made with extreme care and with conscientious acknowledgment of doubts and difficulties in dealing with critical plants.

Two classes of vegetation seem particularly to have attracted the author's notice, and both in a decidedly historical aspect. The one class is that of the alien plants, whose spread from ballast-heaps, &c., is traced; the other is the shore vegetation of a coast which has been much changed both by man and by tidal denudation. There probably exists no "Flora" of any county in Britain which approaches it in interest in either respect, unless it be that of Middlesex by Trimen and Thiselton-Dyer, published in 1869 at the time when Lord de Tabley was at work on what has just been printed.

To the matter which was put into his hands, the editor has wisely added enough to bring the work into line with our present knowledge of Cheshire botany. The biographical notice in its want of facts is a little disappointing; and the attempt to give each plant a binomial English name leads one to a curious and not altogether happy result. These, however, are small matters.

I. H. B.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### Fourier's Series.

THE statement of Fourier's theorem for the special case which has intermittently for some months past been a subject of discussion in NATURE, is as follows:—The function whose value is $\frac{1}{2}(\pi - x)$, when $x$ lies between 0 and $\pi$, and $-\frac{1}{2}(\pi + x)$, when $x$ lies between 0 and $-\pi$, can be expressed by the series $\sum_{k=}^{k=\infty} \frac{\sin kx}{k}$ for values of $x$ which lie between $\pi$ and $-\pi$.

The proof of the theorem, whether in this special case or in more general cases, consists in summing the series; and the result obtained in this special case is that the sum of the series is

$$\begin{array}{ll} \frac{1}{2}(\pi - x), & \text{when } x \text{ lies between 0 and } \pi, \\ -\frac{1}{2}(\pi + x), & \text{when } x \text{ lies between 0 and } -\pi, \\ 0 & \text{, when } x = 0. \end{array}$$

Prof. Michelson has found a difficulty in this result in that, whereas the sum of any number of terms of the series is a continuous function of $x$, the sum of the series is a discontinuous function of $x$. If I have not misunderstood him, he contends that for extremely small positive values of $x$ the sum of the series should be regarded as indeterminate and as having any value between 0 and $\frac{1}{2}\pi$, and I understand him to support this contention by the consideration that when $n$ terms of the series are taken, so that $x$ being extremely small $nx$ is finite, such an indeterminateness is found.

Such a position involves a misconception of the meaning of

the "sum of an infinite series." When $u_1 + u_2 + \dots$ is the series, the terms being uniform functions of $x$, the sum of the series for any value of $x$ is the limit of the sequence of numbers $u_1$, $u_1 + u_2$, $u_1 + u_2 + u_3$, ... in each of which $x$ has the given value; the limit of the sum of the series when $x = 0$, is the result obtained by *first* summing the series for a finite value of $x$, and *afterwards* diminishing $x$ without limit; the sum of the series when $x = 0$ is the result obtained by *first* substituting 0 for $x$ in the functions $u_1$, $u_2$, ... and *afterwards* forming the limit of the sequence $u_1$, $u_1 + u_2$, .... In the example in question, the results thus obtained are $\frac{1}{2}\pi$ and 0 respectively. The results that can be obtained by summing the series to $n$ terms, diminishing $x$ indefinitely, increasing $n$ indefinitely and keeping $nx$ finite, generally do not coincide either with the sum for $x = 0$ or with the limit of the sum for $x = 0$, when these are different. Such results may, as I have pointed out in a previous letter, be useful for purposes of illustration, but they are quite beside the mark when it is a question either of the statement of Fourier's theorem or of the sum of Fourier's series.

M. Poincaré, in his letter printed in NATURE for May 18, does not assert that the sum of the series can be obtained by allowing $x$ to approach zero and $n$ to increase at the same time, in such a way that $nx$ remains finite; but he states that Prof. Michelson is perfectly right in contending that the result of this process is indeterminate. So far as I am aware this contention has not been called in question in the course of the discussion.

## Bessel's Functions.

THE remarks of "C. G. K." (p. 74) concerning the defects of style which are frequently observed in the writings of scientific men, lead me to point out a grammatical error which is creeping into mathematical literature. I allude to the use of the incorrect phrase "Bessel Functions" in the place of "Bessel's Functions."

In certain cases the name of a person may be converted into an adjective by the addition of an appropriate termination, of which such words as *Elizabethan* and *Victorian* are examples; but to use the name itself (which is a noun) as an adjective, is a violation of one of the most elementary rules of grammar.

When the conversion of a proper noun into an adjective would be cumbrous or inelegant, the only correct mode of expression is to use the *genitive* case. If, therefore, we reject such an adjective as "Bessellian" on the ground of its inelegance, we must use the phrase "Bessel's Functions," that is functions of Bessel. The absurdity and incorrectness of the phrase "Bessel Functions" is at once seen by comparing it with such phrases as "*Green* Theorem," "*Chrystal* Algebra," "*Love* Elasticity."

The correct use of the genitive case is a subject upon which considerable misapprehension has existed. Thus we find in the Prayer Book the phrase "For Jesus Christ His sake," instead of "For Jesus Christ's sake." The error arose from the fact that the compilers of the Prayer Book were ignorant that the *'s* is not a conception of the pronoun *his*, but is the old Teutonic genitive which still exists in most German languages.

Fledborough Hall, Holyport, May 28. A. B. BASSET.

## "The Art of Topography."

IN your issue of March 23 (No. 1534, vol. lix.) appears a review of "Recherches sur les Instruments, les Méthodes et le dessin Topographiques, par le Colonel A. Laussedat," signed by "T. H. H." The review brought to my attention several points of interest upon which I beg leave to comment.

Regarding planetable instruments, the reviewer says "that 'Russians and Americans' use very complicated instruments." Of the Russian instruments I have no knowledge, but this is certainly not true of the American.

The U.S. Geological Survey makes use of the planetable to a greater extent than any and all other organisations in America, fully two hundred of these instruments being constantly in use.

The instruments used are remarkable in simplicity and efficiency, are reasonably light, portable and accurate. The instruments are of a model designed by Mr. Willard D. Johnson, of the Survey, and are fully described on pages 79 to 89 of *Monograph* xxii. of the U.S. Geological Survey, entitled "Manual of Topographic Methods," by Mr. Henry Gannett.

This work also treats of the methods of accomplishing topographic mapping by the Geological Survey. Mr. Gannett explains the use made of the planetable, and shows that all work is controlled by points, located by triangulation or other means dependent upon numerical measurements and carefully computed. The triangulation is carried on with eight-inch theodolites reading, by micrometer microscopes, to two seconds.

The instructions to triangulators include the order that points must be selected and arranged so as to best control the area under survey, and that *three* points at least should be located on each atlas sheet of the map. Since these sheets differ in area in different parts of the country, ranging from 1/16 of a square degree to a square degree, the distance between triangulation stations necessarily varies considerably.

After the primary triangulation points are located in an area, dependence upon the planetable is absolute for the "secondary" triangulation within that area, the control, both horizontal and vertical, is carried on by use of this instrument. If the surveyor using a planetable for graphic work starts from accurately located points with check point available, he very soon discovers any "accumulation of error," in that it is impossible to make the several locations check one with another.

In regard to the use of "continuous contours" to express relief, the "Commission of 1826" seems to have drawn the remarkable conclusion that for scales less than 1 : 10,000 this system is insufficient.

The Geological Survey publishes topographic maps which vary in scale between 1 : 9600 and 1 : 250,000 (1 inch to 800 feet and 1 inch to 4 miles about, respectively), and on these maps the contour interval varies between 5 feet and 200 feet. The expression of relief is, I think, in these cases satisfactory, at least so far as giving accurate information is concerned; the artistic effect is very good also, especially when the topographic features are large and the slopes steep, cliffs appearing as broad heavy lines where differentiation of the individual contours is impossible.

About 1890, the use of mercurial barometers was abandoned by the Geological Survey, and trigonometric methods for obtaining heights were adopted. At the present time the primary heights are determined by spirit-levelling, from which elevations are carried in connection with the triangulation or by lines run with vertical angle readings and carefully measured distances. The use of the aneroid barometer is only allowed in inaccessible areas between the known elevations, and must be frequently checked. The experience of the writer in widely separated regions in the United States, in obtaining differences of elevation with the aneroid, leads him to the conclusion that, as a rule, the instrument fails to record differences as accurately when carried from a higher to a lower region as it does when the change of elevation is in the opposite direction. Also, that an aneroid which has been used in a region of elevation of given range must be given time to accommodate itself, if it be required to do good work in a region of greater or less elevation than that in which it has been used. The principle and construction of the aneroid is such that it never can be accepted as an instrument of precision except within well-defined limits, with frequent comparison with known elevations. The Survey has in use several hundred aneroid barometers, but no confidence may be had in any one of them unless frequently checked, as stated. It will be seen that the methods now in use in America agree more closely with those practised by the British Government, at least so far as the Colonial surveys are concerned, than with any other of the European surveys. R. H. C.

## The Heating of the Anti-Kathode in X-Ray Work.

SINCE the beginning of X-ray work the heating of the anti-kathode has caused great difficulty, and with the introduction of the Wehnelt interrupter it is even more important that this should be prevented. In other words, we all along have had more energy from the coil than could be utilised in the Crookes' tube. Many workers like myself have tried to remedy this, and various plans have been adopted to keep the anti-kathode cool. It occurred to me that if we could get a piece of platinum, fused into the glass tube itself, to act as the anti-kathode, and placed opposite the kathode, this object might be attained. Such a tube, after many attempts, has at last been made; and although the first experiments have only been successful in making small tubes, others of a larger size are at present being attempted. The advantage of this method will easily be seen, because the heating of the piece of platinum can be prevented by placing the whole tube in a fluid cooling mixture or otherwise. These tubes are difficult to make at present, but I possess one which has retained its vacuum for some weeks.

## Variation of Species.

ON p. 181 of Wallace's "Darwinism," ed. 1889, this passage occurs:—"Let us suppose that a given species consists of 100,000 individuals of each sex, with only the usual amount of fluctuating external variability. Let a physiological variation arise, so that 10 per cent. of the whole number—10,000 individuals of each sex—while remaining fertile *inter se* become quite sterile with the remaining 90,000. This peculiarity is not correlated with any external differences of form or colour, or with inherent peculiarities of likes or dislikes leading to any choice as to the pairing of the two sets of individuals. We have now to inquire, What would be the result?"

I have here attempted to investigate this question algebraically.

A. We shall suppose, as Dr. Wallace does, that the number of males in the species is the same as the number of females. Each of these numbers we shall denote by unity. For convenience, we shall speak of the number of either sex as the number of the species. Let then

$x$ = the number of the normal species,

and

$y$ = the number of the variant variety,

at any given stage of the change above described.

If in any given generation $(x, y)$, the ratio, which the number of the variant individuals, born in a family of the normal species, bears to the total number of young born in that family, be denoted by $k$; and if $(x', y')$ denote the generation which succeeds $(x, y)$; then must

$$x' : y' :: x^2(1-k) : y^2 + kx^2;$$

with the relation

$$x' + y' = x + y = 1;$$

because the total species remains constant in number of individuals.

Now, if the variants succeed in establishing themselves as a new species, and the above two generations belong to the permanently settled state of the whole species, we must have $x' = x$, and $y' = y$.

Consequently, to determine $x$, $y$ under this condition we have the equations

$$\frac{(1-k)x^2}{x} = \frac{y^2 + kx^2}{y},\quad x + y = 1;$$

$$\therefore\ (1-k)x = 2x^2 - 2x + 1;$$

$$\therefore\ x = \tfrac{1}{4}(3 - k \pm \sqrt{k^2 - 6k + 1}).$$

To take Dr. Wallace's example, put $k = \cdot 1$. Then

$$x = \cdot 88508\ \ldots,\quad y = \cdot 11492\ \ldots;$$

or

$$x = \cdot 56492\ \ldots,\quad y = \cdot 43508\ \ldots.$$

Thus, taking Dr. Wallace's number 100,000, we find that, ultimately, the normal species will number 88,508 and the variant 11,492 These numbers differ but little from Dr. Wallace's, but they represent the final distribution of the original species into two species. Another possible distribution is given by the numbers 56,492 and 43,508. If by any chance the first permanent distribution be disturbed materially, then the total species might reach the second permanent state.

If, however, at any time the parent species were to cease to produce the variants, then the latter would quickly disappear. They could be saved from extinction only by the ceasing of intermarriage between the two species. For, if $(x_n, y_n)$ denote the $n$th generation from the one $(x, y)$ in which the variants ceased to be produced by the normal species, then

$$x_n : y_n :: x^{2^n} : y^{2^n}.$$

If $n = 4$, and $x = \cdot 9$, $y = \cdot 1$, as in Dr. Wallace's case, then

$$x_4 : y_4 :: (\cdot 81)^4 : \cdot 00000001;$$

so that the original species of 100,000 would have no variants left at all. The disappearance of the variants is due to the two facts, (1) that the total number of the two species together is constant, (2) that the number of unfruitful unions is very large in proportion to the number of unions possible to the smaller species. For example, if the variants be ·1 of the whole species, the probability will be that ·9 of their unions will be unfruitful; but that ·9 of the unions of the normal species will not be unfruitful.

B. We shall now consider the case when the unions between the two varieties are not sterile, and the hybrids are also fertile *inter se* and with the parent varieties.

Let the relative, effective, fertility of the hybrids and mongrels, *inter se* and with the parent varieties, be denoted by the factor $k$, which we shall assume to be always less than unity. Also, let the effective fertility of the normal species in the production of variants be denoted by the factor $\mu$; and let $z$ denote the number of the hybrid variety in the generation $(x, y, z)$.

Then the equations which determine the stable and permanent condition, if there be one, are

$$\frac{(1-\mu)x^2}{x} = \frac{y^2 + \mu x^2}{y} = \frac{\{(x+y+z)^2 - x^2 - y^2\} \times k}{z},$$

$$x + y + z = 1. \qquad \ldots\ldots\ldots (1)$$

Put

$$\alpha = 1 - z,\ k' = 1 - k,\ \mu' = 1 - \mu;$$

then

$$\mu' x(1 - k'\alpha) = k, \qquad \ldots\ldots\ldots (2)$$

and

$$\mu' x\alpha = x^2 + (\alpha - x)^2. \qquad \ldots\ldots\ldots (3)$$

Put

$$\beta = (1 - k'\alpha)\mu'\alpha; \qquad \ldots\ldots\ldots (4)$$

then

$$\beta^2 - k(3-\mu)\beta + 2k^2 = 0. \qquad \ldots\ldots (5)$$

Whence

$$\alpha,\ \text{or}\ 1 - z, = \frac{1}{2k'}\left\{1 \pm \sqrt{1 - \frac{4k'\beta}{\mu'}}\right\}, \qquad \ldots (6)$$

and

$$\beta = \frac{k}{2}\left\{3 - \mu \pm \sqrt{\mu^2 - 6\mu + 1}\right\} \qquad \ldots\ldots (7)$$

The roots of $\mu^2 - 6\mu + 1 = 0$ are ·17158 . . . and 5·82842 . . .

As we suppose $\mu$ less than 1, it follows that in no case must $\mu$ exceed the lower root, ·17158 . . . . . . . . . . . . (8)

From (7) it follows that $\beta$ must $> k$.

From (6) it follows that $1 - \mu$ must $> 4k'\beta$, or $= 4k'\beta$;

$\therefore\ 1 - \mu$ must $> 4kk'$; $\therefore\ k$ must not $> \cdot 5$ . . . . . (9)

Also $\beta$ must not $> \dfrac{\mu'}{4k}$, . . . . . . . . . . . . . . . (10)

To take Dr. Wallace's example, put $\mu = \cdot 1$.

We find, then, that $kk'$ must not $> \cdot 225$. If we put $kk' = \cdot 225$, and solve for $k$, we find that

$$k = \cdot 342\ \ldots,\ \text{or}\ \cdot 658\ \ldots.$$

But $kk'$ must not $> \cdot 225$; hence $k$ must not lie between ·342 . . . and ·658 . . .; ∴ by (9) $k$ must not $> \cdot 342$ . . .

Take, for example, $k = \cdot 2$.

Then by (7), $\beta = \cdot 225969$ . . . or ·354031 . . . .

By (10) we must reject the second value of $\beta$.

Adopting the first value, we find from equations (2) and (1) the following two solutions,

$$x = \cdot 798\ \ldots,\ y = \cdot 104\ \ldots,\ z = \cdot 098\ \ldots$$

and

$$x = \cdot 308\ \ldots,\ y = \cdot 040\ \ldots,\ z = \cdot 652\ \ldots.$$

Here the effective fertility of the hybrids, *inter se* and with the parent varieties, must not exceed 34 per cent. of that of the parent varieties; and in no case must it exceed 50 per cent. of the latter. Also, in no case must the parent species supply more than, or even as much as, 18 per cent. of its total progeny to the variant species.

C. If no hybrid unions occur, and the two varieties supply individuals to each other in such a way that, taking the progeny of the generation $(x, y)$, a fraction $\lambda$ of the $x$ progeny belongs to the $y$ variety, while a fraction $\mu$ of the $y$ progeny belongs to the $x$ variety (where $\lambda$ and $\mu$ are proper fractions), it is easy to prove that in the ultimate, established, state of the total species

$$x : y :: \mu : \lambda.$$

Therefore, if $\lambda = \mu$, the species will be, in its final state, equally divided between the two varieties. The equations for the established state are, since now there is no intermarriage,

$$\frac{x - \lambda x + \mu y}{x} = \frac{y - \mu y + \lambda x}{y},\quad x + y = 1;$$

whence

$$\lambda x = \mu y;$$

*i.e.*

$$x : y :: \mu : \lambda.$$

This may also be proved by direct calculation.

Woodroffe, Bournemouth. J. W. SHARPE.

## ON SOME RECENT ADVANCES IN SPECTRUM ANALYSIS RELATING TO INORGANIC AND ORGANIC EVOLUTION.[1]

IN the last lecture I dealt with that new development of spectrum analysis which has enabled us to discuss, with greater fulness than was possible before, the various chemical conditionings in the different regions of our system as marked out for us by the Milky Way. I now have to refer to another development in a somewhat different direction. We have, as I think you will agree, by the discussion of the relation of the celestial bodies of all sorts to the Milky Way, demonstrated that the evolution of the cosmos in all probability took place from the gradual condensation of swarms of meteorites; and that such swarms are still more numerous there, and give rise to the new stars, bright-line stars and variable stars which are most numerous in its plane. When this work was begun our knowledge was so incomplete that a continuous chain of chemical facts was out of the question; but, thanks to the advances to which I have now to refer, we can deal with this cosmical evolution from a chemical standpoint, and what we have to do to-night is to consider the result of this inquiry.

I may begin by saying that now the gaps in our knowledge have been filled up, we find ourselves in the presence of a chemical evolution which is really majestic in its simplicity. Such a chemical evolution was suggested by me many years ago now, to explain the few stellar facts with which we were then familiar; but I do not propose to take up your time with any historical allusions; I must point out, however, that we to-night are in a very much better condition to consider this problem than we have ever been before, because at the present moment we have tens of thousands, I might almost say hundreds of thousands, of coordinated facts to go upon.

The first point I have to refer to is this: we have brought the sun and the stars together into line in all matters relating to the discussion of the effects of higher temperatures. The photographs taken during the recent solar eclipses show that when we deal with the hottest part of the sun that we can get at, which is hotter than that part of the sun which produces the well-known absorption spectrum marked by the so-called Fraunhofer lines, we are not in an unknown territory at all, but are brought face to face with similar phenomena to those in the atmospheres of stars which are hotter than our sun. The bright-line spectrum of the sun's chromosphere seen during an eclipse shows us the effects produced by heat in the hottest part of the sun that we can reach; these we can compare with the dark lines of a star which contains absorption lines very different from those represented by the Fraunhofer lines, and we find that they correspond almost line for line.

In this manner then we have an opportunity of correlating all the facts which have been obtained during the last, let us say, thirty years, in relation to the sun, with more recent facts than have been gathered with regard to the stars. In this work we were, by hypothesis, watching the effects of dissociation as the temperature rose higher and higher; but if we change our point of view, if we consider the phenomena no longer from the point of view of dissociation but from that of evolution, we find at once that the facts recently garnered carry us very far indeed along a new line of thought.

Let me give you an idea of what I mean. Let us deal, for instance, with well-known chemical compounds, say chloride of sodium, that is common salt, and oxide of iron, that is iron-rust. We have no difficulty in recognising the fact that chlorine and sodium in one case and oxygen and iron in the other must have existed before their compounds, common salt and iron rust, could be formed or associated. Water is split into hydrogen and oxygen at a high temperature, so that there is a temperature above which the two gases would remain in contact but uncombined; when the temperature falls water is produced. Dissociation, therefore, in all its stages must reveal to us the forms the coming together of which has produced the thing dissociated or broken up by heat. If this be so, the final products of dissociation or breaking up by heat must be the earliest chemical forms. Hence we must regard the chemical substances which visibly exist alone in the hottest stars as representing the earliest evolutionary forms. That, I think, is pretty obvious.

If we were only dealing with ordinary chemical forms it might be objected that it was only a question of *seeing;* that all chemical substances were really *present* in the reversing layer, that is the part of the atmosphere of the stars which we can study, but some only made their appearance; but I shall show later that the orderly progression includes lines of substances which we cannot see at all and others which we can only see at the highest possible temperatures in our laboratories.

Two or three times over I have used the words "evolution" and "evolutionary forms." What do these words really mean?

Perhaps I can give an idea of this by referring to another line of work altogether in which the word is frequently used and thoroughly understood. It is important that I should do this for another reason, which you will gather later. That line of work has to do, not with inanimate forms, like the chemical elements and the stars, but with living things, with so-called organisms. Some of my audience to-night doubtless remember Huxley's lectures here in 1860 On the Relations of Man to the Lower Animals, and most of you know that what we now recognise as one of the greatest triumphs of the century just ending was the determination of the truth of a so-called "organic evolution" in which we have, I suppose, the most profound revolution in modern thought which the world has seen.

That evolution tells us that each kind of plant and animal was not specially created, but that successive changes of form were brought about by natural causes, and that the march of these forms was from the more simple to the more complex. Organic evolution, in fact, may be defined as the production of new organic forms from others more or less unlike themselves; so that all the present plants and animals are the descendants, through a long series of modifications or transformations, or both, of a limited number of an ancient simpler type. We must not suppose that this change has gone on as if things were simply mounting a ladder; the truth seems to be that we have to deal with a sort of tree with a common root and two main trunks representing animal and vegetable life; each of these is divided into a few main branches, these into a multitude of branchlets, and these into smaller groups of twigs.

This new view represents to us the evolution of the sum of living beings; shows that all kinds of animals and plants have come into existence by the growth and modification of primordial germs. Now I want just to say that this is no new idea, it is the demonstration which is new to us in our present century and generation; we have really to go back to the seventeenth century, if indeed we must not go as far back as Aristotle, for the first germs of it; but with regard to the history, however, I have no time to deal with it. There are two or three points, however, to be considered in regard to this evolution. The individual organic forms need not continuously advance; all that is required is that there shall be a general advance—an advance like that of our modern civilisation—while some individual tribes or nations, as we know, stand still, or become even degenerate. With

[1] A Lecture to Working Men, delivered at the Museum of Practical Geology on Monday, April 24, by Sir Norman Lockyer, K.C.B.

this reservation; the first forms were the simplest. It may be that as yet we know really very little of the dawn of geological history; that the fossiliferous rocks are nowhere near the real base. This conclusion has been derived by Prof. Poulton[1] from the complexity of the forms met with in them; still we find that we have not to deal with such a vast promiscuous association of plants and animals of lowest and highest organisation as we know to-day; we deal relatively only with the simplest. The story both with regard to plants and animals is alike in this respect.

Let me deal with the plants first. The first were aquatic—that is to say, they lived in and on the waters. So far as we know, the first plant life was akin to that of the algæ which include our modern seaweed, moss-like plants followed them, and then ferns, and it is only very much later that the forms we know as seed plants with gaily coloured flowers living on the land made their appearance. The general trend of change amongst the plants has been in the direction of a land vegetation as opposed to one merely in or on the surface of the waters, and some present seaweeds exhibit the initial simplicity of plant-structure which characterised the beginning of vegetable life, while the seed plants I have mentioned are of comparatively late development; but we still have our seaweed; so that with all the change in some directions some forms like the earlier survive.

After this explanation, relating to work in an apparently different direction, you will have no difficulty in understanding the meaning I attach to the word "evolution" in relation to stars and the chemical elements which visibly exist in them, so far as the history of plant change is concerned; but we are not limited to plant life. The same conceptions apply to animal life, and it is important for my subject that I should refer to that also. What do we find there? We are brought face to face with the same progression from simple to complex forms. This is best studied by a reference to the geological record

Stratigraphical geology is neither more nor less than the anatomy of the earth,[2] and the history of the succession of the formations is the history of a succession of such anatomies; or corresponds with development as distinct from generation. In stratigraphical geology, as can be gathered from any book on geology, we find the names of certain beds which contain certain different forms of animal and vegetable life. We begin with the Laurentian and Algonkian and then pass to the Cambrian, then to the Ordovician, the Silurian and Devonian, and so on through a long list of beds and geological strata until we come eventually to the Recent, that is to say, the condition of things which is going on nowadays on the surface of the earth. And if we prefer to map those many different beds into more generic groupings, we begin with the Primary or Palæozoic, we pass on to the Secondary or Mesozoic, and then we finally reach the Tertiary or Cainozoic. The deposition of these beds and of the animal life which has been going on continuously on the surface while those beds have been deposited gives us the various changes and developments which have taken place with regard to animal forms. It is worth while to go a little into details and to indicate the changes in these forms which have taken place, in the most general way. Beginning with the Lower Cambrian, we find that the animal forms were represented by Invertebrata such as Sponges, Corals, Echinoderms, Brachiopods, Mollusca, Crustacea and many early Trilobites; not to mention true Fucoids and other lowly plant-remains. When we come to the Silurian, we find a large accession of the above forms, especially of Corals, Crinoids, and Giant Crustaceans (such as *Pterygotus*) and armoured animals (Ostracodermi) without a lower jaw, or paired fins; the beginnings of Vertebrate life, not yet fully evolved, and one lowly organised group of armoured fishes named *Cyathaspis* (without bone cells in their shelly-shield). Here, too, we meet with the first Air-breathers; the wing of a Cockroach, and several entire and undoubted Scorpions! Thus in addition we get vertebrates as opposed to invertebrates, and the first traces of the fishes. In the advance to the Devonian the fishes (associated with giant Crustacea) predominate; it has been called the age of fishes. In the next series, the Carboniferous, we find the first certain traces of amphibians, of which the early existence is like that of a fish: a state of things illustrated by the frog, which the majority of us in our early days have, I am sure, studied as a tadpole in its early stages; and some of these amphibians still retain fish-like characters. It is not until we arrive at the Permian that the true reptiles are met with, but in the next great series, the Triassic, we meet with a remarkable evolutionary group of Reptiles, the Theriodontia, or beast-toothed animals, because (unique among reptiles) they possess a dentition like a dog or a lion, with incisors, canines and cheek-teeth; the precursors doubtless of the succeeding Mammalian type. We pass easily thus from the reptiles to mammals which are related to them; for instance, the ornithorhynchus and the echidna are both Australian mammals which bring forth their young within the egg as do the reptiles. Well, after that we begin to deal with birds. The early birds were strikingly reptilian in some of their characters; and the pterodactyle, which many of you may have seen remains of in different museums, was really a winged reptile and not a bird. From that we gather that mammals and birds are variants of reptiles. When we progress from the Jurassic to the Recent, we find man making his appearance as a direct descendant of all those early forms. There is not much new in this. This, as I have said, is what Huxley largely demonstrated in this theatre thirty-nine years ago in a previous course of these Lectures to Working Men.

When we come to study the life-history of the various forms brought before us by the geological strata, we find it to vary considerably, a fact indicated by the presence or absence of the different genera in the various strata. We find that the trilobites, for instance, only appear in the very early geological formations: there is no trace of them in the recent, but if we take the annelids we find that they are continuous from the earliest to the latest formations; we still have our worms. Again we find that certain other organic forms made their appearance very low down in the time scale, forms which were not represented at all in the earlier Cambrian and Silurian, and that some of these are continuous to the present day. Let us take the story of the fishes. A great many fishes made their appearance at the Devonian stage, there were few in the Silurian; some of these stopped there, whereas others have been continued from the Devonian times to our own. Take, for instance, the Australian mudfish *Ceratodus*; to judge from the teeth this fish might well have lived on unchanged from late Palæozoic times until the present day! We see there is a tremendous variation of possible life-range, so to speak, with regard to these different forms, and the plant record, although necessarily more imperfect than the animal on account of the nature of the organism, tells the same story in its fragmentary evidence. In that way, then, the geologist has been able to bring before us the continuity of life in various forms from the most ancient geological strata to the most recent. The record may be incomplete, but is complete enough for my purpose. But that is not the only evidence of evolution to which I can refer.

The teachings of embryology confirm the argument based upon the study of geology, and suggest that the life-history of the earth is reproduced in the life-history of individuals. The processes of organic growth or em-

[1] Presidential Address, Section D, British Association Meeting at Liverpool, 1896.
[2] Huxley, *Q. J. G. S.*, xxv. p. xliii.

bryonic development present a remarkable uniformity throughout the whole of the zoological series; and although knowledge is still limited, some authorities hold that there is the closest possible connection between the development of the individual and the development of the whole series of animal life. There are others, however, who do not regard the argument derived from embryology as a very convincing one. However this may be, if we study the embryos of the tortoise, fowl, dog and man, we find that there is a wonderful similarity between them at a certain stage. At a further stage of development the similarity is still borne out. This does not mean that a vertebrate animal during its development first of all becomes a tortoise, and then the various animals which are represented by these embryos; it simply means that they are all related inasmuch as there is continuity.

After these references to plants and animals it should be clear what organic evolution really is, and therefore what evolution is generally. I wish next to bring before you some considerations having relation to the stratigraphical record.

The question for us now is—Is there any equivalent to this in the inorganic world? or, to put it in another way, in those facts which have been revealed to us by the presence of the various chemical forms in the stellar strata represented by stars of varying temperatures? That is the question.

When I referred in my last course of Lectures here to cosmical evolution, I said that there we dealt with a continuity of effects accompanied by considerable changes of temperature; from the gradual coming together of meteoritic swarms until eventually we had a mass of matter cold and dark in space. The various stars which represent the different changes have been got out and have, in fact, been arranged along a so-called temperature curve. As we ascend one branch of this curve the stars get gradually hotter and hotter till ultimately at the top we find the hottest stars that we know of. Then on the descending branch are represented the cooling bodies, and finally they come down in temperature until we reach that of a dark world like the companion of Sirius, of our own moon, and the planet in which we dwell.

*We can now deal with all these bodies in relation to their chemistry.* We find that in the hottest stars we get a very small number of chemical elements; as we come down from the hottest star to the cooler ones the number of spectral lines increases, and with the number of lines of course the number of chemical elements. I will only refer to the known substances, it looks as if at present we have still many unknowns to battle with. In the hottest stars of all, we deal with a form of hydrogen which we do not know anything about here (but which we suppose to be due to the presence of a very high temperature), hydrogen as we know it, the cleveite gases, and magnesium and calcium in forms which are difficult to get here; we think we get them by using the highest temperatures available in our laboratories. In the stars of the next lower temperature we find the existence of these things continued in addition to the introduction of oxygen, nitrogen and carbon. In the next cooler stars we get silicium added; in the next we get the forms of iron, titanium, copper and manganese which we can produce at the very highest temperatures in our laboratories; and it is only when we come to stars much cooler that we find the ordinary indications of iron, calcium and manganese and other metals. All these, therefore, seem to be forms produced by the running down of temperature. As certain new forms are introduced at each stage, so certain old forms disappear. In order to connect this work with the stratigraphical work, to which I have referred, I have recently tried to define these various star-stages by means of their chemical forms which they reveal to us; so that we may treat these stellar strata, so to speak, as the equivalent of the geological strata to which I have already called your attention.

From the hottest to the coldest stars I have found ten groups so distinct from each other chemically that they require to be dealt with separately as completely as do the Cambrian and the Silurian formations. Imitating the geologist, I have given the following names to these groups or genera beginning with the hottest, that is the oldest dealing with the running down of temperature:—Argonian, Alnitamian, Achernian, Algolian, Markabian [a "break in strata"], Sirian, Procyonian, Arcturian (solar), Piscian.

I have gone further, and defined the chemical nature of these stellar genera as the biologist defines the nature of any of his organic genera; we can say, for instance, that the Achernian stars contain chiefly hydrogen, nitrogen, oxygen and carbon, and to a certain less extent they contain proto-magnesium, proto-calcium, silicium and sodium,[1] and possibly chlorine and lithium; so that at last, by means of this recent development of spectrum analysis, we have been able really to do for the various stars what the biologist a good many years ago did for the geological strata.

Now, considering this inorganic evolution from the chemical point of view, there are several matters which merit consideration. We shall not get much help by thinking along several obvious lines, for the reason that in the stars we are dealing with transcendental temperatures; for instance, we must not make too much of the difference between gases and solids, because, at high temperatures all the chemical elements known to us as solids are just as gaseous as the gases themselves; that is to say, they exist as gases; at a high temperature, everything, of course, will put on the nature of gas. Those substances with the lowest melting points, such as lithium and sodium, will, of course, under our present conditions put on the gaseous condition very much more readily than other substances like iron and platinum, but those are considerations which need not be taken into account in relation to very high stellar temperatures; of course, there would be no solids at a temperature of 10,000° C.

Then with regard to metals and non-metals. Here again we really are not greatly helped by this distinction. The general conception of a metal is that it is a solid, and that therefore a thing that is not a solid is not a metal; but the chemical evidence for the metallic nature of hydrogen has been enlarged upon by several very distinguished chemists. With regard to non-metals, there are certainly very many. Carbon is supposed to be a non-metal, and it is remarkable that, so far as the stellar evidence which I have brought before you has gone, carbon seems to be the only certain representative of that group. I want to point out specially that the table of the chemical definitions of the various stellar genera which I show you, which contains nothing but hard facts, is perhaps, like the geological record, more important on account of what it indicates as to the presence of the chemical elements in the stars than it is for what it omits.

There are a great many reasons why some of the substances which may exist in these stars should not make their appearance. I wish to enlarge upon the fact that, seeing the very small range of our photographs of stellar spectra, and seeing that it does not at all follow that the particular crucial lines of the various chemical substances will reveal themselves in that particular part of the spectrum which we can photograph, that the negative evidence is of very much less importance than the positive evidence. I think it is very likely, for instance, that we must add lithium to

[1] Campbell, "Astronomy and Astro-physics," 1894, xiii. p. 395.

the substances which we find in the table, we must certainly add sodium, and also aluminium, and chlorine possibly, but about sulphur at present I have no certain knowledge; you will see the reason for these references later on. At all events, we can with the greatest confidence point out the remarkable absence of substances of high atomic weights, and the extraordinary thing that the metals magnesium and calcium undoubtedly began their existence in the hottest stars long before, apparently, there is any obvious trace of many of the other metals which a chemist would certainly have been looking out for.

In relation to this new work, the first point to make is that the chemical forms we see in the hottest stars are amongst the simplest. What is the justification for this statement? Well, there are two reasons. The chemist will acknowledge that if there be such a thing as chemical evolution, an element of low atomic weight is simpler, that is, less massive, than an element of high atomic weight. If we rely upon spectrum analysis we can say, when dealing with the question of "series," about which I hope to say something in my next lecture, that the elements which have the smallest number of "series" are in all probability simpler than those which have a large number, and this is still truer when we find that all the lines in the spectrum of a substance can be included in those rhythmical series, as happens in the case of the cleveite gases. So that the first stage of inorganic evolution, if there has been such an evolution, is certainly a stage of simplest forms as in organic evolution.

The next point is that the astronomical record, studied from the evolution point of view, is in other ways on all-fours with the geological record. We get the same changes of forms, I may say that we get the sudden breaks in forms, disappearances of old accompanied by appearances of new forms, and with this we get, whether we consider the atomic weight point of view or the series point of view, a growth of complexity.

The geological story is exactly reproduced. Now, here it is obvious that a very important point comes in. In inorganic evolution we are dealing with a great running down of temperature; how tremendous, no man can say. We know the temperature of our earth, but we do not know, and we can not define, the temperatures of the hottest stars. So that how great the temperature of the earth may once have been, supposing it to be represented by the present temperature of the hottest star, no man knows anything with certainty.

With regard to organic evolution, however, which has to do with the plant world and the animal world, there can have been no such running down of temperature at all. The temperature must have been practically constant. Please bear that in mind, because I shall have to refer to it later on.

It is proper that I should say that just as the work of Darwin in the nineteenth century was foreshadowed by seventeenth century suggestions, so the stellar demonstration which I have brought before you to-night has been preceded by hypotheses distinctly in the same direction. The first stage of chemistry, as you know, was alchemy. Alchemy concerned itself with transmutations, but it was found very early that the real function of the later science of chemistry was to study *simplifications*, and, of course, to do this to the utmost we want precisely those enormous differences in temperature which it appears the stars alone place at our disposal.

With regard to the general question of inorganic evolution, the first idea was thrown out in the year 1815 by Prout, who, in consequence of the low atomic weight of hydrogen, suggested that that gas was really the primary element, and that all the others, defined by their different atomic weights, were really aggregations of hydrogen, the complexity of the aggregation being determined by the atomic weight; that is to say, the element with an atomic weight of twenty contained twenty hydrogen units; with an atomic weight of forty it contained forty, and so on. The reply to that was that very minute work showed that the chemical elements, when they were properly purified and examined with the greatest care, did not give exactly whole numbers representing their atomic weights. They were so and so plus a decimal, which might be very near the zero point, or half-way between, and that was supposed to be a crushing answer to Prout's view. The next view, which included the same idea—that is to say, a physical connection between these different things as opposed to the view that they were manufactured articles, special creations, each without any relation whatever to the other, was suggested by Döbereiner in 1817, and the idea was expanded by Pettenkofer in 1850. Both pointed out that there were groups of three elements, such as lithium, sodium, and potassium, numerically connected; that is, their atomic weights being 7, 23, and 39, the central atomic weight was exactly the mean of the other two, $7 + 39 = 46$, divided by 2, we get 23. Another way, however, of showing that is that $7 + 16 = 23$, and $23 + 16 = 39$; the latter method suggests a possible addition of something with an atomic weight of 16.

In 1862 de Chancourtois came to the conclusion that the relations between the properties of the various chemical elements were really simple geometrical relations. That, you see, is a much broader view. It is not till 1864 that we come to the so-called "periodic law," which was first suggested by Newlands, and elaborated by Mendeléeff in 1869. According to this law, the chemical and physical properties of the elements are periodic functions of their atomic weights. Lothar Meyer afterwards went into this matter, and obtained some very interesting results from the point of view of atomic volumes. He showed that if we plot the atomic volumes of the different elements, arranged according to their atomic weights from left to right, there is a certain periodicity in the apices of the curve indicating the highest atomic volumes.

So far there was no reference to the action of temperature in relation to this, but in 1873 I suggested that we must have a fall of temperature in stars, and that the greater complexity in the spectra of certain stars was probably due to this fall of temperature. This idea was ultimately utilised by Sir William Crookes in an interesting variation of the periodic law, in which he assumes that temperature plays a part in bringing about the changes in the characters of the elements. Brodie, in 1880, came to the conclusion that the elements were certainly not elementary, because in what he called a "chemical calculus" he had to assume that certain substances, supposed to be elements, were really not so; and he then threw out the very pregnant idea that possibly in some of the hotter stars some of these elements which he predicted might be found. Nine years afterwards, Rydberg, one of the most industrious investigators of the question of "series" to which I have referred, stated that most of the phenomena of series could be explained by supposing that hydrogen was really the initial element, and that the other substances were really compounds of hydrogen; so that you observe he came back to Prout's first view in 1815.

All these ideas imply a continuous action, and suggest that there was some original stuff which was continuously formed into something more complex as time went on. That is to say, that the existence of our chemical elements as we know them does not depend upon their having been separately manufactured, but that they are the result of the working of a general law, as in the case of plants and animals.

You see at once that the stellar facts which have already been brought before you are entirely in harmony with the highest chemical thought, and indeed establish

the correctness of its major contention. We may be said to pass from chemical speculation to a solid chain of facts, which doubtless will be strengthened and lengthened as time goes on. In all these changes we seem to be in the presence of a series of what chemists call polymerisations, that is, roughly, a series of doublings. The greater complexities may also have been brought about by the union of different substances. In either case, as temperature is reduced, we get a possibility of combinations which was not present before; so that more and more complex forms are produced.

That brings us to a possibility of considering the processes of inorganic evolution in relation to those of organic evolution. I have already referred to the fundamental difference in the conditions. We had a running down of temperature which no one could define in the case of the stars; in the case of the organic evolution going on under our present conditions, we cannot be very much removed from the temperature conditions of the Cambrian formations. That is a point which I have made before, and it is important to insist upon it; clearly there cannot have been any very great change of temperature during the whole cycle of organic life. Previous to it we have found complexity brought about by doublings and combinations, the result being, as I have already mentioned, more complex forms. Of course, at the dawn of organic life on the surface of the earth there may have been residua of the earlier chemical forms; that is to say, not all the elements which we found in the hottest stars had combined to form the substances of which the earth was composed. However this may be, the work of organic evolution, unlike that of inorganic evolution, must have been done under widely different temperature conditions, but the result has been the same; it has since provided us with another succession of forms getting more complex as time has gone on, and there is still a residuum of early forms. We are led then to the conclusion that life in its various forms on this planet, now acknowledged to be the work of evolution, was an appendix, as it were, to the work of inorganic evolution carried on in a perfectly different way. Although the way was different, still nature is so parsimonious in her methods—she never does a thing in two ways that can be as well done in one—that I have no doubt that when these matters come to be considered, as they are bound to be considered with the progress of our knowledge, we shall find a great number of parallels; but I am not looking for these parallels now. What I wish to drive at is a chemical point of view which I think of some importance in relation to what has gone before; it is a point which I wish to make depending upon the existence of those elements which make their appearance in the hottest stars. In inorganic forms, in those represented to us in the hottest stars and the stars of gradually lower temperature, we have forms produced by a junction of like or unlike forms. Very good; but the more of these junctions the more the early forms must have disappeared, unless we may take it that they may have been made occasionally to reappear by the destruction of the later forms: that is a point to bear in mind. If the simpler forms must go on doubling to provide the more advanced forms, then if all the simpler forms are so used up there will be none left, and the only chance of getting the simpler forms again is to destroy something which had been previously made; and we can quite understand, of course, that there were many conditions of this destruction possible at the time when the crust of the earth was being formed. But however that may be, the gaseous elements with the non-gaseous elements first formed, would be the chief chemical substances on the surface and over it. Now the substances over the crust, of course, would be the gases, oxygen, hydrogen, nitrogen, and from the stars we can suggest carbon combined with them; that is to say, hydrocarbons, carbonic acid, and so on. On the surface, whether the surface be one of land or water, we should expect, in addition to the low melting point metals lithium and sodium, those two metals which we know existed in the hottest stars long before the others, magnesium and calcium. I have told you that lithium probably and sodium certainly exist in some of the relatively hot stars; the evidence also suggests sulphur, and this is rendered more probable because of the simplicity of its spectrum-series. Now these are very remarkable associations, and seem far away from ordinary chemical considerations, but they are the most important substances in sea water.

*Constituents of Sea Water.*

| Carbonate of lime ... ... ... ... | 0·34 |

The most easily thinkable evolution under these circumstances would be that of organisms built up of these chemical forms, chiefly because they would represent the more mobile or the more plastic materials. You would not expect evolution to have begun in iron, you would have expected it to have begun in something which was the most mobile and the most plastic. The available matter then for this evolution would be those gases plus those metals and those non-metals to which I have referred. Now, mark this. Suppose you have this evolution; if the forms so composed were to be multiplied indefinitely, the available material would be used up and organic evolution would be brought just as certainly to a dead-lock as the inorganic evolution was brought to a dead-lock when there was no possibility of any considerable reduction of temperature. We should expect a tendency to growth among the organic molecules, I dare not call it an inherited tendency, but I feel almost inclined to do so, having the growth of crystals in mind. Now, suppose that after you have got these new organic forms, the results instead of being stable were emphatically unstable, and still better, suppose you could induce a dissolution or the destruction of parts or wholes, progress would always continue to be possible, and indeed it might be accelerated.[1]

The new organic molecules would ultimately not have the first user of the chemical forms left available by the inorganic evolution, but they would have the user of the gases and other substances produced by the dissolution of their predecessors. They would be shoddy chemical forms, it is true, but shoddy forms would be better than none. Under these circumstances and in this way, the organic kingdom would be allowed to go on; in other words, the dissolution of parts or wholes of the new organisms would not merely be an advantage to the race, but might even be an essential condition for its continuance.

It therefore looks very much as if we can really go

[1] My friend and colleague, Prof. Howes, has called my attention in this connection to Prof. Weismann's views ("Weismann on Heredity," vol. i. p. 112), who seems to have arrived at somewhat similar conclusions, though by a vastly different road. He says, in his "Essay on Life and Death," "In my opinion life became limited in its duration not because it was contrary to its very nature to be unlimited, but because an unlimited persistence of the individual would be a luxury without a purpose."

The general view I have put forward, however, suggests that perhaps it was not so much a question of *luxury* for the living as one of *necessity* in order that others might live; it was a case of *mors janua vitae*.

The whole question turns upon the presence or absence, in all regions, of an excess of the early chemical forms ready to be used up *in all necessary proportions*. Hence it may turn out that the difficulty was much greater for land- than for sea-forms, that is, that dissolution of parts or wholes of land-forms proceeded with the greater rapidity. It is a question of the possibility of continuous assimilation (see Dantec, "La Sexualité," p. 11), and the word "parts" which I have used refers to the somatic cells, and not to the "immortal" part of living organisms.

back as far as these very early stages of life on our planet to apply those lines of Tennyson :—

> "So careful of the type she seems,
> So careless of the single life."

We have arrived, then, at a condition in which the same material may be worked up over and over again; in this way ultimately higher forms might be produced. Now, if to this dissolution, as a means of giving us new material, we add reproduction, then we can go a stage very much further. If we take bi-partition, which was the first method of multiplication, as we know both in the vegetable and animal world, we have a multiplication of forms by halving instead of the inorganic multiplication of forms by doubling, then we can have a very much increased rate of advance.

These then, roughly, are the conclusions as to an organic evolution which are suggested by the stellar evidence as to inorganic evolution, and the collocation of the simplest forms noted in the hottest stars.

Let us turn finally to the facts. Biologists, as I have said before, are very much more happy than astronomers and chemists, because they can see their units. A chemist professes to believe in nothing which he does not get in a bottle, although I have never yet seen the chemist who was ever happy enough to bottle an atom or a molecule as such ; but the superstition still remains with them, and they profess to believe in nothing that they cannot see. Now, the organic cell is the unit of the biologist, which is itself a congeries of subordinate entities, as a molecule is made up of its elementary atoms, manifesting the properties common to living matter in all its forms.

The characteristic general feature of the vegetable activity of the plant forms is their feeding upon gases and liquids, including sea-water. The progress of research greatly strengthens the view that there was a common life plasm, out of which both the vegetable and the animal kingdoms have developed. Be that as it may, you see the vegetable grows upon these chemical forms to which I have referred, and the animal feeds either upon the plant or upon other animals which have in their turn fed upon plants ; so that there we get the real chemical structure of the protoplasm, of the real life unit, in our organic evolution.

The last question, then, that I have to touch upon is this. Is there any chemical relation between the chemical composition of the organic cell and the reversing layers of the hottest stars—the reversing layer being that part of a star's anatomy by which we define the different genera ?

When we come to consider the chemical composition of this cell we find it consists of one or more forms of a complex compound of carbon, hydrogen, oxygen, nitrogen, with water, called protein ; and protoplasm, of which you have all heard, the common basis of vegetable and animal life, is thus composed. This substance is liable to waste and disintegration by oxidation, and there may be a concomitant reintegration of it by the assimilation of new matter.

The marvellous molecular complexity of the so-called simple cell may be gathered from the following formulæ for hæmoglobin :

| | | | | | | |
|---|---|---|---|---|---|---|
| Man ... | C 600 | H 960 | N 154 | Fe 1 | S 3 | O 179 |
| Horse ... | C 712 | H 1130 | N 214 | Fe 1 | S 2 | O 245.[1] |

Various different percentage compositions have been given of this protoplasm, but I really need not refer you to them. It is more important to consider the other chemical substances which go to form it, for there are others beside which it is of interest to study from our stellar point of view. I quote from Mr. Sheridan Lea.[2]

"Proteids ordinarily leave on ignition a variable quantity of ash. In the case of egg-albumin the principal constituents of the ash are CHLORIDES of SODIUM and potassium, the latter exceeding the former in amount. The remainder consists of SODIUM and potassium, in combination with phosphoric, sulphuric and CARBONIC acids, and very small quantities of CALCIUM, MAGNESIUM and iron, in union with the same acids. There may be also a trace of SILICA."

My point is that the more one inquires into the chemistry of these things the more we come back to our stellar point of view and to the fact that, taking the simplicity of chemical form as determined by the appearance of these different chemical substances in the hottest stars as opposed to the cooler ones, and in relation to the "series" of spectra which they produce, we come to the conclusion that the first organic life was an interaction somehow or other between the undoubted earliest chemical forms. Not only have we hydrogen, oxygen and nitrogen among the gases common to the organic cell and the hottest stars, but those substances in addition which I have indicated by capitals.

Surely we have here, I think, thanks to some of the recent advances made by spectrum analysis, a quite new bond between man and the stars.

We shall consider in the next lecture the simplicity of chemical forms as evidenced, not by atomic weight, but by the study of spectrum-series, to which I have already made two or three references.

## *THE BERLIN TUBERCULOSIS CONGRESS* (1899).

THE Congress, which has just brought its proceedings to a close, was not, as has been frequently stated in the medical and lay press, an International Congress ; it was a German Congress to which foreign delegates and communications were invited. The mass of communications were made in German, this being the official language of the Congress ; a few, some half-dozen, in English and French. The necessity, or at any rate advisability, of discoursing in German, may account for the very meagre manner in which English medicine was represented either privately or officially. It seemed somewhat anomalous that the staff of only one London consumption hospital (the North London) was represented at the Congress. Further, the English doctors practising at foreign health resorts, who probably have unrivalled opportunities for observing the different phases of consumption, and the influence of treatment upon them amongst better class patients, were for the most part conspicuous by their absence. This nonchalance is to be regretted, especially as the hygienic treatment of phthisis, a relatively, at any rate in its systematic form, new development, occupied some 50 per cent. of the whole time of the Congress.

The enormous amount of material at the disposal of the Committee was classified in two ways. All papers were in the first instance denominated as lectures ("Referate"), or discussion communications. For the former twenty minutes was allowed, for the latter ten. The subject-matter was divided into five Sections. I. Extent and Spread of Tuberculosis. II. Aetiology. III. Prophylaxis. IV. Treatment. V. Sanatorium Treatment.

Section I.—Dr. Bollingen (Munich) read a paper upon tuberculosis amongst domestic animals, and its relationship to tubercular disease in man. Amongst many important points, the lecturer emphasised the importance of milk as a source of tubercular infection to men, directly and indirectly. Indirectly in the sense that tuberculosis is very common amongst pigs, who get infected in considerable numbers from being fed with the milk of tuberculous cows. Dr. Krieger (Strassburg) discussed the re-

lationship of external surroundings to the spread of tubercular disease. The author pointed out the unsatisfactory nature of statistics upon this subject, owing to the complexity of apparently simple factors. Constant attendance upon phthisical patients in badly ventilated rooms, and certain occupations giving rise to irritation of respiratory tract from dust, metallic or otherwise, were however, according to the lecturer, potent factors in the spread of tuberculosis. Papers followed upon tubercular disease among various employés, notably knife and sword makers, bookbinders, compositors, and cigar makers.

Section II.—Aetiology.—This Section was opened by Prof. Flügge (Breslau), who read a well-appreciated paper upon the relation of the tubercle bacillus to tuberculosis. Recent work has not in this connection modified to any extent the dicta originally enunciated by Koch. The tubercle bacillus is the immediate cause of tuberculosis, and arises in practically all cases from a tuberculous animal. Its parasitic nature is obligatory, *i.e.* except in the case of artificial cultures the bacillus cannot develop outside the animal organism. By means of artificial cultures it is possible to modify the tubercle bacillus in certain ways, notably with regard to its morphological character, and its virulence. Prof. C. Frankel (Halle) discoursed eloquently upon the nature and *modus operandi* of tubercular infection. He pointed out that outside the animal body tubercle bacilli die in from six to seven months, the important factors in killing them being light, and the fact that they lose their water by evaporation, and with it their life. As a result of this it is, as a rule, only the immediate neighbourhood of the patient, from 1 to 1½ metre, that is infective. Infection usually takes place through the infected person inhaling fresh and moist tubercle bacilli which ("infected drops") have been ejected usually during a coughing fit, also by the inhalation of dust contaminated with dried sputum. He further pointed out that man was relatively unsusceptible to tubercular infection, and that, as a rule, it was only by repeated and continued inhalation, &c., of tubercle bacilli that infection occurred.

A subject of great interest to physicians was considered at some length by Prof. Pfeiffer (Berlin), viz. "mixed infection." Consumption, as we know it, is rarely due simply to the tubercle bacillus, but to the superadded action of other infective organisms. As many as twenty-four different varieties of bacilli have been obtained from the sputum of a phthisical patient. An important practical point brought out by the lecturer was that cases of mixed infection ought to be recognised in consumptive hospitals, and isolated, as they may be a source of danger to phthisical patients; that is, these latter may get a mixed infection superadded to their other troubles. Prof. Löffler read a short paper upon heredity, immunity and disposition in their relation to tuberculosis. Hereditary tuberculosis in the sense, for instance, of congenital syphilis, is unknown. In this disease hereditary influences probably play a relatively small part as such. Tuberculosis occurs in members of the same family, mostly because by living together the members infect each other. Prof. Löffler quoted one family as an instance of this. The father and mother, two daughters and seven sons, all died of phthisis. The family consisted of fifty-eight other members, not one of whom was tuberculous. The infection was entirely confined to the members of the family living together. The lecturer emphasised the fact that no natural immunity to tuberculosis exists. Dr. von Zander gave some aetiological statistics of tuberculosis. Out of 312 cases investigated, 116 were communicated from man to man; amongst these infection between sisters occurred the most often.

Section III.—Prophylaxis.—Dr. Roth (Potsdam) discussed certain rules for the prevention of tubercular infection. These mostly consisted of measures directed to the disposal of the sputum, and the use of a cloth in front of the mouth during coughing fits, to limit the area of "infective drop" dispersion. Prof. v. Leube (Wurzburg) considered the prophylactive methods against tuberculosis in hospitals. If measures such as those mentioned above are thoroughly carried out, tubercular patients need not be isolated from the general hospital inmates. Care should be taken by attendants and nurses especially in dusting rooms, when it would be advisable for them to have their mouth and nose protected by a mask.

All members of the Congress listened most attentively to a short paper, by Prof. Virchow, upon the prevention of tuberculosis in so far as concerns food. Prof. Virchow considered four articles of diet: (1) beef, (2) pork, (3) poultry, (4) milk. Of these he regarded milk as far the most important. He advised a more careful and systematic exclusion (under central control) of tubercular meat and cattle, and the rejection of milk from all cows which reacted to the tuberculin list. Even these measures the author described as palliative, the only curative measure being the killing of all animals that reacted to the tubercular list. In this connection, Dr. Schumburg (Hannover) gave the result of his researches as to whether ordinary butcher's meat contained tubercle bacilli. The result of twenty-four inoculations (intra-peritoneal) of guinea-pigs with the juice of twelve different meat samples, was that two animals died of purulent peritonitis, two greatly diminished in weight, the remaining twenty remained well. Dr. Baer (Berlin) discussed the much-vexed question of alcohol and tuberculosis. He concludes, upon apparently very insufficient grounds, that alcohol in the consumptive sanatoria should only be used as medicine under the most urgent circumstances. Dr. Ritter read a paper upon the protection of children from tuberculosis. An interesting communication upon the diminution in the total death-rate from consumption due to modern methods of treatment was made by Dr. Julius Lehmann (Copenhagen). Dr. Kuno Obermüller discussed some interesting investigations upon the presence of the tubercle bacillus in ordinary market milk and butter. He centrifugalised the milk, and injected less than ·5 cc. of the sediment into the peritoneal cavity of guinea-pigs. The milk was taken from a dairy which supplies Berlin with 80,000 litres daily. The result was that 30 per cent. of the injected animals died in from eleven to thirteen weeks of tuberculosis. The milk used was the best and most costly infant milk. According to the author, Berlin butter is also largely infected with virulent tubercle bacilli, which are quite distinct from the so-called butter bacillus. Dr. Hambleton, President of the Polytechnic Physical Development Society, was the author of a communication on the prevention of pulmonary tuberculosis. One of the most potent factors to this end is, according to the author, chest development, and he took this opportunity of bringing before the notice of the Congress the work of the Society in this direction. This method had, according to the author, been most successful in preventing and even arresting tuberculosis among the employés of trades having an injurious effect upon the respiratory organs.

F. W. Tunnicliffe.

## THE JUBILEE OF SIR GEORGE GABRIEL STOKES.

The celebrations in connection with the jubilee of Sir George Gabriel Stokes, who has occupied the Lucasian Chair of Mathematics at Cambridge University since 1849, begin this afternoon (Thursday) with the delivery by Prof. Cornu, of the École Polytechnique, Paris, of the Rede Lecture. Prof. Cornu has chosen as his subject, "The Wave Theory of Light and its Influence on Moder Physics."

This evening a banquet will be given by Pembroke College, at which many of the distinguished guests and older colleagues of Sir George will be entertained in the hall of the College, which he entered as a freshman in 1837. During the evening the University will entertain about one thousand visitors and residents at a conversazione in the Fitzwilliam Museum, an interesting feature of which will be the presentation by Lord Kelvin of two busts, executed by Mr. Hamo Thorneycroft, of Sir George Stokes—one to the University, and the other to Pembroke College.

On Friday at 11 a.m., in the Senate House, the addresses of congratulation will be presented to the Vice-Chancellor, and handed by him to Sir George Stokes. Some sixty-five different institutions from all parts of the world will be represented. At 7 o'clock the delegates and their hosts will be entertained at luncheon by the Vice-Chancellor at Downing College, and at 2.45 a second congregation will be held in the Senate House, at which the Chancellor, the Duke of Devonshire, will preside. At this congregation, the honorary degree of Sc.D. will be conferred on Profs. A. Cornu and J. G. Darboux of Paris, on Prof. A. A. Michelson of Chicago, on Prof. M. G. Mittag-Leffler of Stockholm, on Prof. G. H. Quincke of Heidelberg, and on Prof. W. Voigt of Göttingen. A gold medal struck in honour of the occasion will be presented to Sir George Stokes by the Chancellor, and replicas will be sent to all the Universities and learned societies who are represented at the Jubilee.

Later in the afternoon a garden party will be held in the grounds of Pembroke College, and in the evening the University will entertain the delegates and guests at a dinner given in the hall of Trinity College. The Chancellor will take the chair, and amongst other distinguished guests who have accepted invitations may be mentioned the Lord Lieutenant of Cambridgeshire, the Bishop of Ely, the President of the Royal Society, the Vice-Chancellors of the Universities of Oxford, Aberdeen, and London, the Earl of Rosse, Lord Kelvin, Lord Rayleigh, Lord Blythswood, the Provost of Trinity College, Dublin, Monsignor Molloy, and many others.

There will be a special meeting of the Cambridge Philosophical Society, at which some of the foreign members will, it is expected, read papers. This will probably take place on Monday, June 5. Many of the guests will leave Cambridge for London to take part in the anniversary celebrations of the Royal Institution.

## *NOTES.*

A MEETING for discussion will be held at the Royal Society on Thursday next, June 8. The subject to be discussed—preventive inoculation—will be introduced by M. Haffkine.

ARRANGEMENTS for the sixty-ninth annual meeting of the British Association at Dover, in September next, are making satisfactory progress. The local committees are actively at work, and in response to the appeal of the hospitality committees over 1500*l.* has already been subscribed. As previously announced, the president of the meeting will be Prof. Michael Foster, and the presidents of the various sections are to be:—Mathematical and physical science, Prof. J. H. Poynting; chemistry, Mr. Horace T. Brown; geology, Sir Archibald Geikie; zoology, Mr. Adam Sedgwick; geography, Sir John Murray, K.C.B.; economical science, Mr. Henry Higgs; mechanical science, Sir William H. White; anthropology, Mr. C. H. Read; physiology, Mr. J. N. Langley; botany, Sir George King, K.C.I.E. The first general meeting will be held at the Connaught Hall on Wednesday, September 13, at 8 p.m. precisely, when Prof. Michael Foster will deliver an address; on Thursday evening, September 14, at 8.30 p.m., there will be a soirée in the School of Art; on Friday evening, September 15, at 8.30 p.m., a discourse will be delivered by Prof. Charles Richet, on "La vibration nerveuse"; on Monday evening, September 18, at 8.30 p.m., a discourse will be delivered by Prof. Fleming, F.R.S., on "The Centenary of the Electric Current"; on Tuesday evening, September 19, at 8.30 p.m., there will be a soirée in the School of Art; on Wednesday, September 20, the concluding general meeting will be held at 2.30 p.m. Excursions to places of interest in the neighbourhood of Dover and to the continent will be made on Thursday, September 21. Members of the Association Française pour l'Avancement des Sciences will visit Dover on Saturday, September 16. Members of the British Association are invited to visit Boulogne on Thursday, September 21.

THE following naturalists have been elected foreign members of the Linnean Society:—M. Adrien Franchet of Paris, Prof. Emil Christian Hansen of Copenhagen, Dr. Seiitsiro Ikeno of the Imperial University, Tokyo; Prof. Eduard von Martens of Berlin, and Prof. Georg Ossian Sars of Christiania.

THE gold medal of the Linnean Society, which was presented at the anniversary meeting on May 24, has this year been awarded to Mr. John Gilbert Baker, of Kew, in recognition of his important contributions to botanical science. Amongst these may be mentioned his *Synopsis Filicum*, his monographs of the daffodils and roses, handbooks on the *Amaryllideae*, *Irideae*, *Bromeliceae*, and the fern allies; three volumes on the *Compositae* in Martins's "Flora Brasiliensis," and several papers on Malagasy botany, the Flora of Mauritius and the Seychelles, the Bulbous Flora of the Cape, and the *Leguminosae* of British India, "Flora of the English Lake Country," and numerous papers communicated to the *Journal* of the Linnean Society, the *Journal of Botany*, and other periodicals.

AT the annual meeting of the Victoria Institute, to be held on June 19, an address will be delivered by Sir Richard Temple.

THE anniversary meeting of the Royal Geographical Society will be held on Monday next, June 5. The Society's annual conversazione will be held in the Natural History Museum on Wednesday, June 7.

THERE will be no Friday evening discourse at the Royal Institution to-morrow (June 2), as Mr. H. G. Wells, who was to lecture on "The Discovery of the Future," is in too weak a state of health to do so.

AT the recent annual meeting of the American Academy of Art and Sciences, Mr. Alexander Agassiz was elected president of the Academy. The Rumford medal was awarded to Mr. Charles F. Brush, of Cleveland, for "the practical development of electrical arc lighting."

A REUTER telegram dated Helsingfors, May 26, says:—"The collected pieces of the aerolite which fell at Bjurholm some time ago have been sent here, and placed in the geological museum. The largest piece is said to weigh 206 Russian pounds, while all the parts together weigh 850 lbs."

DR. L. A. BAUER has resigned his position as assistant professor of mathematics and mathematical physics at the University of Cincinnati, in order to accept the position of chief of the newly-formed division of terrestrial magnetism of the United States Coast and Geodetic Survey. To this division has been assigned the magnetic survey of the United States and the countries under its jurisdiction, and the establishment of magnetic observatories. Dr. Bauer has also been appointed lecturer in

terrestrial magnetism at the Johns Hopkins University. The journal, *Terrestrial Magnetism and Atmospheric Electricity*, beginning with the June number, will be issued hereafter from the Johns Hopkins University Press, Dr. Bauer continuing as editor-in-chief.

ON the evening of May 13 a meeting of the New York Electrical Society was held at Madison Square Garden, where an Electrical Exhibition is now going on, to celebrate the centennial of the discovery of the electric battery by Alessandro Volta. Mr. Edison sent a letter expressing his admiration of Volta's investigations and researches, and associating himself with the fraternal messages which were sent to the Italian electrical society and to the Electrical Exhibition at Como, the birthplace of both Volta and the voltaic cell. The New York *Electrical Review* states the following message was cabled to the Italian Premier :—"The electricians of America, celebrating the Volta Centennial in New York, extend heartiest congratulations to the fellow-workers in Italy, and, in doing so, desire to express the hope that the work of such pioneers as Galvani, Volta, Pacinetti and Ferraris may be renewed and repeated by other members of the Italian race in the century which is now dawning. America owes a deep debt of gratitude to Italy for electrical discoveries, which have done so much to abridge distance and add to the welfare of mankind. Please communicate these sentiments to King Humbert in the name of the New York Electrical Society.—Gano S. Dunn, President."

THE Berlin correspondent of the *Times* states that the committee which is organising the German Antarctic expedition has decided that the expedition is to be composed of one ship only. The vessel, which is to be built entirely of wood, is to be laid down this autumn. The expedition is to be ready to start in the autumn of 1901, and is to be away two years altogether. After touching at the Cape, the expedition is to make for the Antarctic continent south of the Kerguelen Islands, and there establish a scientific station at some point suitable for wintering. A pack of Siberian dogs is to be taken, and dashes will be made on sledges towards the South Pole and the south magnetic pole. Meteorological observations will also be made from a captive balloon. After the breaking up of their winter quarters, the expedition will attempt to make as complete a survey as possible of the coast line of the Antarctic continent. As already announced in these columns, the leader of the expedition is to be Dr. von Drygalski, who conducted the German exploration of Greenland in the years 1891-93. The committee expresses great satisfaction that the English Antarctic expedition has at last been definitely decided on, and points out that the value of the two sets of meteorological observations will be greatly enhanced by their being carried on simultaneously.

AN Industrial Exhibition organised by the Artist Club was opened at the Crystal Palace on Tuesday by the Duke and Duchess of Connaught. The exhibition has been furnished by about one hundred leading British manufacturers, and the element of competition has been eliminated by only including one set of exhibits of any particular industry. Engineering appliances of various kinds are prominent. Railway and steamship interests are also well represented. Refrigerating processes employed in the Colonial meat trade are shown in operation. There is also an interesting display of printing machinery at work, and of type-setting by Linotype machines. Electricity figures in the exhibition, and a number of novel devices of various kinds are to be seen. As an example of quick work in photography, it is worth mention that the opening ceremony was photographed and projected upon the screen by the Biograph and Mutoscope Company before the Royal party left the Crystal Palace three hours later.

AT the annual general meeting of the Institution of Electrical Engineers, held on Thursday last, the announcement was made that the premiums for papers read during the session 1898-99 had been awarded by the Council as follows :—The "Institution Premium," value 25*l.*, to Mr. P. V. McMahon, for his paper on "Electric Locomotives in Practice, and Tractive Resistance in Tunnels, and Notes on Locomotive Design"; the "Paris Electrical Exhibition Premium," value raised to 20*l.*, to Mr. W. Duddell and Mr. E. W. Marchant, for their paper, "Experiments on Alternate Current Arcs by aid of Oscillographs"; two "Fahie Premiums," none having been awarded in 1898, of 10*l.* each, one to Prof. O. Lodge, F.R.S., and one to Mr. G. Marconi, for their papers entitled respectively "Improvements in Magnetic Space Telegraphy" and "Wireless Telegraphy"; two extra premiums of 10*l.* each, one to Mrs. Ayrton for her paper on "The Hissing of the Electric Arc," the other to Mr. J. Elton Young, for his paper on "Capacity Measurements of Long Submarine Cables"; the Senior "Students' Premium," value 10*l.*, to Mr. W. G. Royal-Dawson, student, for his paper on "Alternating Currents of very High Frequency"; the second "Students' Premium," increased in value to 10*l.*, to Messrs. M. R. Gardner and W. P. Hewgrave Graham, for their paper on "The Synchronising of Alternators"; the third "Students' Premium," value 5*l.*, to Mr. Leonard Wilson, student, for his paper on "The Effect of Governors on the Parallel Running of Alternators"; extra "Students' Premium," value 4*l.*, to Mr. L. R. Morshead, for his paper on "Enclosed Arc Lamps," and an extra "Students' Premium," value 3*l.*, to Mr. H. M. Dowsett, student, for his paper on "Electricity Meters"; the Salomons Scholarship for 1899-1900, value 50*l.*, was awarded to Mr. H. J. Thomson, a student of the Central Technical College.

THE hydrographical surveys made in H.M. surveying vessels during the year 1898, and referred to in the recent report by the Hydrographer of the Admiralty, led to a number of important results. Resurveys of parts of the Thames and Medway show that remarkable changes have taken place. An examination of the Shingles patch in the Duke of Edinburgh Channel has shown that this patch now has 15 feet of water on it, and its steady growth since 1882 has reduced the width of the Duke of Edinburgh Channel, at present the principal passage into the Thames for heavy vessels, from $1\frac{1}{2}$ miles to about $\frac{1}{2}$ a mile. The total obliteration of the passage, which seems by no means impossible, would entail a long circuit at the time of low water to large vessels to or from the Thames and Medway, but the operations of nature in this estuary are far too great to be controlled by works. A resurvey was made of the Middle Swin. This passage way, the main route for the enormous trade between London and the north, has of late years much contracted and shoaled, and gives considerable anxiety to the Trinity House, as, if necessary to alter the route, many changes in lights and buoys would be necessary to make another passage safe. There is now very little more than 19 feet on the bar at low water.

A SERIES of observations with a deep-sea current meter, carried out in the large Strait of Bab-el-Mandeb by the officers of H.M. surveying vessel *Stork*, are referred to by the Hydrographer in his report. The observations, which are valuable as bearing on the system of circulation in the oceans, have been published in a report on the under-currents of the Straits of Bab-el-Mandeb; but the broad result may be briefly stated. There was a permanent current on the surface setting *into* the Red Sea of about $1\frac{1}{2}$ knots an hour. There was at 105 fathoms depth a permanent current of about the same velocity setting *outwards*. The tidal stream was about $1\frac{1}{4}$ knots at its maximum, and flowed for about twelve hours each way, as might

be expected from the fact that in this locality there is practically only one tide in the day. This tidal stream prevails to the bottom with variations of strength. Somewhere about 75 fathoms below the surface is the dividing line between the two permanent currents, but there were not sufficient observations to determine the exact depth with any precision.

IN the current number of the *Psychological Review*, Prof. Wesley Mills points out that in investigating the psychology of animals, care must be taken to observe them under conditions as nearly approaching their normal surroundings as possible. He maintains that to place a cat in a box, as has been done, and then to expect it to act naturally, is about as reasonable as to enclose a living man in a coffin, lower him, against his will, into the earth, and attempt to deduce normal psychology from his conduct. Besides, the highest animals should be compared with the lowest human beings before maintaining that there is an essential difference between the respective mental lives of animals and the human race.

A SERIES of instructive experiments on young chicks have been made by Dr. Edward Thorndike. About sixty chicks of all ages were studied, and some remarkable instances of instinctive muscular coordination and emotional reaction were observed. A four days' chick will jump down a distance eight times his own height without hurting himself. Thrown into a pond, he will make straight for the shore, while an adult hen would float about aimlessly. For the first four or five days there is no fear of strange objects or sounds, such as the sight of a man or a hawk's cry. Instinct does not always lead to the same reaction. A loud sound may make one chick run, another crouch, another give the danger call, and another do nothing whatever.

AT Montgomery, Alabama, the daily forecasts of the U.S. Weather Bureau are shown on all street letter-boxes. The postman who collects the letters also fixes the forecast cards in position, so that the morning predictions of weather become known throughout the city by about 1 p.m. of the date of issue.

THE *Mitteilungen aus den deutschen Schutzgebieten* contains a valuable contribution to our knowledge of the Harmattan winds in the form of three short papers by competent observers in Togoland, and a discussion of the material by Dr. von Danckelmann. The investigation leads to the conclusion that the Harmattan, strictly so called, is a strengthening of the general north to south movement of the atmosphere prevalent in the western Sudan between October and April, caused by special modifications in the distribution of pressure which are not yet fully explained. The excessive dryness of the air, and its dustiness, are due to the origin of the current in the regions north of the bend of the Niger; and it is shown that the wind may penetrate into coast districts normally exposed to the influence of the moist sea breeze. The characteristic low morning temperatures are probably due to excessive radiation, but the point requires further elucidation.

WE have received the seventh annual report of the Sonnblick Society, for the year 1898, containing the meteorological observations on the summit of the Sonnblick mountain, lat. 47° 3′ N., long. 12° 57′ E., altitude 10,191 feet, and also at two intermediate stations, respectively nearly 4000 and 3000 feet above the sea. The observations have been carried on with great care and regularity, and the observatory on the summit is now under the entire management of the Austrian Meteorological Society. The difficulty of carrying on the work of this important station may be gauged from the following results for the year. The mean annual temperature was 22°·3, the absolute maximum 46°·4, and the minimum minus 13°·7. Fog occurred on 250 days, and rain (or snow) on 200 days. The report also contains useful detailed information respecting the mineral products of the neighbourhood, and particulars relating to the high observatories in the Alps.

THE Central Physical Observatory of St. Petersburg has recently published its *Annals* for the year 1897, consisting of two large quarto volumes. The first part contains the meteorological and magnetic observations made at the stations of the First Order, and the extraordinary observations at stations of the Second and Third Orders; for several stations, observations are published for every hour. The second part contains the meteorological observations of the Second Order stations, arranged according to the international scheme, and gives the observations made three times a day, and results for eighty-two stations, and a *résumé* of the monthly and annual means for 661 stations. Each set of observations is preceded by a detailed introduction, giving particulars of the methods employed and of the instruments used. In accordance with the decision of the Meteorological Conference at Paris in 1896, a useful list is added of all the periodical publications appearing in Russia which contain meteorological observations. The Director of the Meteorological Service is General M. Rykatcheff, Member of the Imperial Academy of Sciences of St. Petersburg.

DR. KEILHACK contributes a short paper on the hydrography of north-western Germany to the *Verhandlungen* of the Berlin Geographical Society. The relation of the later glacial deposits to the existing valleys and lakes is discussed, and a map shows the supposed successive positions of the inland ice, and the courses of the longitudinal valleys associated with each phase of its movement.

WE have received No. 3 of the "Current Papers" published by Mr. H. C. Russell in the *Proceedings* of the Royal Society of New South Wales, along with which is a chart showing the tracks of floats between September 1896 and September 1898. The additional information confirms the result stated in the second paper, that the rate of drift increases with latitude south of 30° S. One float gave an average rate of 12·4 miles per day in latitude 47°·16 S.

CHARLES WACHSMUTH (of Burlington, Iowa), who died in 1896, had for forty years zealously studied the fossil Crinoidea of the older rocks of North America, being assisted during the latter half of the period by Mr. Frank Springer. The labours of the two on "The North American *Crinoidea camerata*" have been published in an important monograph containing 838 pp. and 83 plates: and this work has now been subjected to an elaborate criticism by Mr. F. A. Bather, of the British Museum (Natural History), who has reprinted his series of articles, which were published in the *Geological Magazine* (1898–99). These critical essays form an important contribution to the study of the Crinoidea, and they are appropriately accompanied by a portrait and brief biography of Wachsmuth.

MR. ARNOLD HAGUE, in his presidential address to the Geological Society of Washington (February 1899), took as his subject the "Early Tertiary Volcanoes of the Absaroka Range." This range extends along the east side of the Yellowstone Park, in the State of Wyoming, and several of the higher peaks and the long western spurs slope gradually towards the Park, and lie within its borders. The Absarokas present a high plateau, ranging from 10,000 to over 12,000 feet above sea-level, and composed of agglomerates, tuffs, and lava flows, based upon Archæan and Palæozoic rocks, and including masses of intrusive igneous rock. The volcanic materials constitute the bulk of the mountains, and they were ejected from numerous vents and fissures at several successive epochs, mainly in the following order: early acid breccia, early basic breccia, early basalt sheets,

late acid breccia, late basic breccia, and late basalt sheets. Evidence of the long duration of the period of volcanic activity is furnished by the remains of plants found at different horizons; over 150 species having been identified, many of them new to science. In one instance, a grand old tree, *Sequoia magnifica*, was found firmly imbedded in the early basic breccia.

IN NATURE for March 9 we gave a short account of the late Prof. Cope's researches on the Vertebrate remains from the Port Kennedy bone deposit in Pennsylvania. We have since received the detailed account of the excavations carried on in 1894-96 by Mr. Henry C. Mercer (*Journ. Acad. Nat. Sc.*, Philadelphia, vol. xi. part 2, April 1899). The results lead to the conclusion that the original configuration of the fissure in which the remains were obtained was that of a deep, well-like chasm opening vertically downward from the sloping surface of a hill, and that the animals stampeded by a flood had rushed to their destruction into the abyss. We have previously mentioned the principal fossil remains obtained. Of these, no less than 377 individuals and 66 species were recognised, of which latter 40 are extinct. No traces of man were discovered, and the general evidence favours the view that the fauna is of earlier date than that which witnessed the presence of man on the American continent.

A RECORD of the work accomplished in the chemical laboratory of the Austrian Geological Survey during the year 1898 is summarised in the Director's Annual Report (*Verhandlungen der k. k. geol. Reichsanstalt*, No. 1, 1899). In addition to the petrographical examination of many rock-specimens, the official work comprised the analysis of no less than 203 samples, such as coals, rocks, ores, and waters. Additional researches, carried out for scientific purposes, are also recorded. Many samples of the materials employed in the construction of the new Danube embankments were examined and reported upon by Dr. v. John, who also concluded the analyses of various Bohemian mineral waters. The results of this last work are published in the September number of the *Jahrbuch*, 1898. Of special economic value are Herr Aug. Rosiwal's experiments for ascertaining methods which shall furnish definite standards whereby all the factors of stability determining the technical utility of building stones may be accurately measured. Some interesting results attained in this connection have already appeared in the *Verhandlungen*, Nos. 5 and 6, 1898.

WE have recently received from the publishers parts 38-40 of Prof. Enrico Morselli's "Antropologia Generale," now in course of publication at Turin. As these fasciculi deal with the intricate problem of man's evolution from the lower animals, they are of more than ordinary interest. The author has done wisely in reproducing a large number of the phylogenetic trees published by modern zoologists, thus giving his readers an opportunity of seeing in what respects they agree or differ from one another. Manifestly, however, his sympathies are with Haeckel's tree of mammals, in which, as is well known, the marsupials form an early offshoot from the main stem. As regards the anthropoids themselves, the author adopts Schlosser's tree, in which a primitive gibbon (*Prothylobates*) is taken as a starting point, from which the gibbons rise as one branch, while *Dryopithecus* forms the main stem. This latter is continued directly upwards to give rise to the orang and chimpanzee, while on one side branches the gorilla, and on the other *Pithecanthropus* and *Homo*. The weak point of this is the wide separation of the chimpanzee and the gorilla. Apart from this, the gibbon-like character in the skull of *Pithecanthropus* (which can scarcely be regarded as generically distinct from *Homa*, unless mental characteristics be taken into account) affords considerable support to the general plan of the phylogeny.

TWO reprints from the *Botanical Gazette* have reached us, by Prof. C. J. Chamberlain and Prof. J. M. Coulter, both referring to the phenomena of fertilisation and embryology in the Coniferæ.

THAT patient observer, Mr. Thomas Meehan, continues, in the *Proceedings* of the Academy of Natural Sciences of Philadelphia, his contributions to the life-history of plants, mostly relating to the phenomena of fertilisation.

THE most recently published part of Engler's *Botanische Jahrbücher*, vol. xxvi. Heft 5, is chiefly occupied with the conclusion of Kränzlin's Orchidaceæ of Guatemala and adjacent countries, and a further instalment of the editor's monograph of the Araceæ. There are also revisions of the genera *Philodendron*, *Dieffenbachia*, and *Tropaeolum*.

FOR the past ten years experiments have been carried on, on an extended scale, to test the suitability of the soil and climate of Indiana for the production of beet-sugar. The results of these experiments are now published in *Bulletin* No. 68 of the Purdue University Experiment Station (Lafayette, Ind.). They show that, wherever the needful precautions have been observed, beets of satisfactory character have been produced in every section of the State, and that it is probable that Indiana can produce enough beets of satisfactory quality to furnish the raw material for a large number of factories.

THE third part of Drs. D. S. Jordan and B. W. Evermann's "The Fishes of North and Middle America," being a descriptive catalogue of the species of fish-like vertebrates found in the waters of North America, north of the Isthmus of Panama, has been issued by the Smithsonian Institution as *Bulletin* No. 47 of the U.S. National Museum.

IT is a little surprising that Wiedemann and Ebert's "Physikalisches Practikum," the fourth edition of which has just been published by Friedrich Vieweg and Son, Brunswick, has not been translated into English. The volume contains a well-arranged and complete course of laboratory work suitable for students who are already familiar with elementary physical operations. Physical-chemical experiments receive particular attention.

MR. C. BAKER has issued a new catalogue of microscopes and accessory apparatus. Many instruments for histological and bacteriological work are included in the catalogue, and outfits suitable for various technical purposes. It is evident from the catalogue that, apart from the medical practitioner, naturalist and amateur, the microscope is being more and more used in trade and professional work.

THIRTEEN important memoirs are published in the *Atti* of the Naples Academy of Physical and Mathematical Sciences (1899, ser. ii. vol. ix). Among the subjects dealt with are: remains of great Pleistocene lakes and rivers in southern Italy, with special reference to the geological conditions which produced such plains as the great Vallone di Diano (full descriptions, with maps, are given of the Agri, Mercure, and Noce); chemical analyses of the waters of the hot springs of Iscia; contribution to the biology of ferns; flora of the basin of the Liri; and fossil fishes of the Eocene chalk of Gassino, Piedmont. The remainder of the memoirs deal with mathematical and geometrical subjects.

WITHOUT disparaging the Smithsonian Institution in the slightest degree, it may be said that the most valuable part of the Annual Report is the appendix, which comprises a selection of interesting memoirs upon scientific subjects. The report for 1897, just distributed, contains no less than thirty-eight memoirs of this kind, dealing with the position and progress of various

branches of science. The memoirs are "not for the specialist, but interesting and popular expositions of what the specialist knows to be sound and opportune." A number of the memoirs are reprints of addresses and articles which have appeared in NATURE, some are original articles, and others are translations or reprints from contributions to various scientific publications. Almost every phase of scientific activity seems to be included among the papers, and many subjects are illustrated by fine half-tone pictures. The Smithsonian Institution does good service to science by the publication of these sound and instructive surveys of the state of natural knowledge.

THE additions to the Zoological Society's Gardens during the past week include a Smooth-headed Capuchin (*Cebus monachus*) from South-east Brazil, presented by Mr. Herbert Gibson; a Palm Squirrel (*Sciurus palmarum*) from India, presented by Miss Aggie O'Connor; a Kinkajou (*Cercoleptes caudivolvulus*, ♀) from South America, presented by Mr. J. J. Quelch; a Mexican Guan (*Ortalis vetula*) from Cartagena, Colombia, presented by Captain W. H. Milner; a Martinique Gallinule (*Ionornis martinicus*), captured at sea, presented by Mr. H. O. Milner; a Leith's Tortoise (*Testudo leithi*) from Egypt, presented by Mr. S. S. Flower; a Black-tailed Wallaby (*Macropus ualabatus*, ♀) from New South Wales, three Rabbit-eared Bandicoots (*Peragale lagotis*, 3 ♂), two Spotted Bower Birds (*Chlamydodera maculata*) from Australia, two Westermann's Cassowaries (*Casuarius westermanni*) from New Guinea, a White-throated Monitor (*Varanus albigularis*) from South Africa, two Starred Tortoises (*Testudo elegans*) from India, four Elephantine Tortoises (*Testudo elephantina*) from the Aldabra Islands, deposited.

## OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN JUNE:—

June 1. 14h. 53m. to 15h. 40m. Occultation of the star 19 Piscium (mag. 5·2) by the moon.

7. 16h. 43m. to 17h. 53m. Partial eclipse of the sun visible at Greenwich. The greatest phase occurs at 17h. 17m., at which time 0·188 (nearly one-fifth) of the sun's disc will be obscured. At places N.W. of Greenwich the eclipse will be of somewhat greater magnitude.

11. 2h. Saturn in opposition to the sun.

15. Illuminated portion of the disc of Venus 0·904, of Mars 0·913.

20. 11h. 30m. Minimum of the variable star Algol (β Persei).

22. 7h. Saturn in conjunction with the moon.

23. 8h. 19m. Minimum of the variable star Algol (β Persei).

23. 10h. 34m. to 11h. 41m. Occultation of B.A.C. 6343 (mag. 5·8) by the moon.

24. 13h. 17m. to 14h. 12m. Occultation of *f* Sagittarii (mag. 5·1) by the moon.

25. 10h. 45m. to 11h. 48m. Occultation of B.A.C. 7145 (mag. 6·0) by the moon.

27. 12h. 59m. to 14h. 2m. Occultation of κ Aquarii (mag. 5·5) by the moon.

28. 11h. 22m. to 12h. 10m. Occultation of κ Piscium (mag. 5) by the moon.

COMET 1899 *a* (SWIFT).—

*Ephemeris for 12h. Berlin Mean Time.*

| 1899. | R.A. h. m. s. | Decl. ° ′ | Br. |
|---|---|---|---|
| June 1 | 17 58 35 | + 56 13·1 | |
| 2 | 17 36 8 | 55 13·8 | 1·34 |
| 3 | 17 15 28 | 54 1·7 | |
| 4 | 16 56 46 | 52 39·2 | 1·18 |

The comet is now passing with a greatly accelerated motion in a south-westerly direction. During the week it will traverse the constellations Draco and Herculis; on the 1st it passes close to ξ Draconis, while on the 8th it will be a little more than 1° north-west of φ Herculis. In *Ast. Nach.*, No. 3567, Prof. A. A. Nijland, of Utrecht, says that, viewed with a finder of 74 mm. aperture on May 5, the comet appeared about 5·5 mag., having a tail about 1°·5 in length.

TEMPEL'S COMET (1873 II.).—

*Ephemeris for 12h. Paris Mean Time.*

| 15 | 19 54 47·2 | − 5 12 25 | |

As the comet approaches perihelion (June 18) it is rapidly becoming brighter, and should now be visible with small instruments. It reached its highest northerly declination on May 26, and is now travelling to the south-east through Aquila into the head of Capricornus.

NEW VARIABLE OF ALGOL TYPE.—M. Ceraski, of the Moscow Observatory, writes in *Astr. Nach.* (Bd. 149, No. 3567), announcing the discovery of a new variable of the Algol type in the constellation Cygnus. The star was detected by the varying intensity of its image on photographs taken during May and July 1898. Its position is

B.D. + 45°·3062. 1855. R.A. = 20h. 2m. 24·5s.
Decl. = + 45° 52·9.

Its magnitude is usually about 8·6, but on May 8 this year it was observed to be at minimum about 13·4h., Moscow mean time, its light then being nearly two magnitudes fainter than the normal.

VARIABLE RADIAL VELOCITY OF ζ GEMINORUM.—Prof. W. W. Campbell has called attention to this star in a paper communicated to the *Astrophysical Journal* (vol. ix. p. 86, 1899), where he gives the results of measures on three photographs. In *Astr. Nach.* (Bd. 149, No. 3565), M. A. Belopolsky gives the results of an extensive series of measures he has been able to obtain with the 30-inch refractor and two-prism spectrograph of the Pulkowa Observatory. The individual observations are given, and also a summation in the form of a table showing the radial velocities at stated intervals from minimum. This latter is as follows:—

| Interval from minimum | Velocity | Interval from minimum | Velocity |
|---|---|---|---|
| d. h. | | d. h. | |
| 0 2 | + 4·76 g.M. | 5 1 | − 2·70 g.M. |
| 0 12 | + 2·86 | 6 19 | + 1·96 |
| 1 12 | + 0·71 | 8 1 | + 3·00 |
| 2 1 | + 0·68 | 8 5 | + 3·02 |
| 3 1 | + 0·04 | 9 6 | + 5·06 |
| 3 12 | + 0·50 | 9 15 | + 4·41 |
| 4 1 | − 0·40 | 10 2 | + 4·11 |
| 4 13 | + 0·34 | | |

Prof. Campbell's maximum and minimum values were 20 kil. and 6 kil. respectively.

## THE RESULTS OF THE "VALDIVIA" EXPEDITION.

DR. SUPAN gives the following summary (based on the official report in the *Reichs-Anzeiger* of March 25) of the chief results of the German expedition in the *Valdivia* to Antarctic waters, in the April number of *Petermann's Mitteilungen*.

(1) Rediscovery and determination of position of Bouvet Island, first discovered by Bouvet in 1739, and sighted since then only by Lindsay (1808) and Norris (1825). The island, which lies in lat. 54° 26′ S., long. 3° 24′ E., and is 9½ kilo-

metres from E. to W. and 8 kilometres from N. to S., is a volcanic mountain, the edge of the crater rising to a height of 935 metres on the northern side. It is entirely covered with ice, which comes down to sea-level, and presents a steep wall to the sea: it would seem from this that in this region a tongue of polar cold projects northwards, a conclusion supported by the serial temperature observations. No trace of vegetation could be recognised with the telescope, and animal life appeared to be exceedingly scanty. No definite information was obtained as to the existence of Thompson Island.

(2) Enderby Land was not visited, as the course was again turned northward at lat. 64° S., but the samples of the sea-bottom yielded evidence that the land is not volcanic. Along the edge of the pack-ice the bottom was covered with diatom ooze, mixed with a larger proportion of clay the nearer Enderby Land was approached. In lat. 63° 17′ S., long. 57° 51′ E., material from ground-moraines, carried to sea by icebergs, was obtained; this consisted of gneiss, granite, schists, and one large piece of red sandstone.

(3) *Climate.*—The zone of fresh westerly winds and low barometer extends south of Africa only to lat. 55° S., and of Kerguelen only to 56½° S.; south of this a belt of calms and light variable winds extends to 60° S., and beyond 60° S. the prevailing winds are easterly. In other parts of the Southern Ocean, the westerly winds extend further south, to 60° and 64° S. latitude. Hence it may be supposed that the position of the Antarctic anticyclone is towards the western part of the Indian Ocean, and not directly over the pole.

In November 1898 the limit of drift ice was found in long. 7° E., to be in lat. 56¾° S. On the voyage from the most southerly point in the neighbourhood of Enderby Land, no icebergs were met with north of 61° 22′ S.

(4) *Oceanography.*—Amongst the most important achievements of the *Valdivia* expedition is the making of a large number of new soundings, with the discovery of an extensive deep-water area. It has hitherto been assumed that the sea-bottom rose rapidly towards the south from the Eastern Atlantic and the western part of the Indian Ocean, but it now seems likely that deep water extends from both these basins into Antarctic latitudes. Kerguelen, and the Crozet and Prince Edward Islands were regarded as projections on the margin of a supposed Antarctic plateau, and this idea had obtained so strong a hold that both V. v. Haardt (1895) and Fricker (1898) simply ignored the soundings of the *Challenger* in their maps, although these had shown depths of over 3000 metres in the Indian Ocean between long. 80° and 95° E. and lat. 60° and 66° S. In the regions sounded by the *Valdivia*, between 7° and 53° E. long., the depth has been found to exceed 5000 metres.

South of the fifty-sixth parallel, the bottom temperature was everywhere below 0° C., but nowhere below −0°·5 C. The serial temperatures in 63° S. lat., 54° E. long., in the month of December, gave the following distribution: (*a*) a surface layer, 120 metres thick, with temperatures between 0° C. and −1°·7 C.; (*b*) an intermediate layer, about 2200 metres thick, with temperatures above 0° C., and rising to 1°·7 C.; (*c*) a bottom layer of equal or greater thickness with temperatures below 0° C., but never colder than −0°·5. Temperature fell from the surface down to 80 metres, then rose to 1200 metres, and then again fell slowly to the bottom. The same arrangement was found further to the west, but the temperatures were somewhat lower, and again to the east, in the track of the *Challenger*; but in the latter case the cold surface layer is thicker, and the warm layer usually reaches to the bottom (3000 to 3300 metres), the cold under-layer being only met with in a sounding of over 3600 metres. The lowest temperature observed by the *Challenger* was −1°·7, the highest only 1°·4. The sea in the region of Enderby Land would thus seem to be favoured by relatively high temperatures, and it remains to bring this into direct relation to the warm Kerguelen stream: this must be done by more observations to the south of Kerguelen.

(5) *Marine Biogeography.*—The quantity of plankton increases down to about 2000 metres, diminishing rapidly at greater depths, although no level is destitute of animal life. The quantity of vegetable plankton, on the other hand, reaches its lowest within 300 or 400 metres of the surface. The characteristic of the Antarctic plankton is the abundance of diatoms, and the occurrence of special forms: the appearance of the Antarctic type begins as far north as 40° S., but in 50° S. the presence of forms belonging to warmer seas is still noticeable.

## THE WEARING AWAY OF SAND BEACHES.

THE rate of erosion of cliffs and land bordering on the sea, caused by the action of the waves, has been the subject of frequent investigation, and numerous records exist as to the rate at which the land is being encroached on by the sea. On low flat coasts the means of ascertaining the result of the contest between the sea and the land is more difficult to ascertain. The ordinary means of measurement is by a comparison of old charts, which are seldom trustworthy for this purpose. These charts being for navigable purposes, the depth of the water and the position of objects on shore forming sea marks were the subjects for which accuracy alone was required. The same remarks apply to old plans of estates and manors which were intended to delineate the property of the owners, the sea shore below high water not being a matter requiring trustworthy accuracy.

The results obtained by the Department of the Waterstaat in Holland, from periodical measurements of the coast adjacent to the North Sea, are therefore of great interest as showing the effect of the sea on flat beaches in low countries.

Between the years 1843–46, the Department caused to be placed all along the Dutch coast, extending from the Helder to the Hook of Holland, a distance of 75 miles, at the foot of the sand hills, oak posts at intervals of one kilometre (·62 mile) to form a permanent base line; and from these, at regular intervals, measurements have been periodically taken to the foot of the dunes on the land side, and to the low water line on the sea side.

The results are recorded in the *Proceedings* of the Dutch Institution of Civil Engineers.[1]

They are also set out in considerable detail, and tables given for the different periods, in the report of a Commission appointed to investigate the shell fishery of the coast, issued in 1896.[2]

The coast between the two parts named forms the arc of a very large circle, the depth of the embayment in the centre being 5½ miles. The main direction for the southern part faces about N.W., and of the northern part W.N.W. The winds which have most effect on the coast are those from the S.W., changing round to N.W.

The set of the flood tide is from south to north, the range decreasing from 5 feet at the Hook of Holland to 4¼ feet at the Texel. The coast line is bordered seaward by a sand beach extending from 300 to 350 feet to low water, lying at a slope of about 1 in 70; and on the land side by sand dunes, which vary from 1 to 3 miles in width and from 40 to 50 feet in height. These decrease in size towards the Texel.

With the exception of the detrital matter brought down in suspension by the river Maas, there is no source for a supply of material to feed the beach. The cliffs which border the French coast, from which the shingle and sand on the beach there is derived, terminate at Sangatte. The drift of the shingle and sand derived from the erosion of these cliffs extends only for a limited distance, and dies out a little beyond Calais and Dunkirk.

As regards the Belgian coast, the beach along which consists entirely of sand, from comparisons made by the Government engineers a few years ago of the various charts and plans dating from the beginning of the present century, and from a comparison of surveys of the coast made in 1833 and 1870, the conclusion was arrived at that no material alteration in the beach of the Belgian coast has taken place, so far as any means of comparison existed; and this was confirmed by measurements, taken in 1833 and 1870, of the height of the beach at the groynes at Ostend, Heyst and Wendyke, which showed that there had been no material alteration in the form of the beach.

The Dutch coast, between the periods to which the present investigations extend, has been subjected to two disturbing elements, in addition to one abnormally heavy gale in December 1894. The opening out of the new water way to Rotterdam through the Hook of Holland, and the construction of the harbour at Ymuiden for the entrance to the Amsterdam Canal, with the long piers extending across the beach, led to a considerable transposition of material at those parts of the shore; but the effect was local, and extended only over a short distance.

As a general result, the measurements show that during the last half-century, on the Dutch coast, the sea has been

[1] "Tidschrift Van het Koningklijk. Instituut Van Ingenieurs" (1883).
[2] "Uitkomst Van het Onderzoek of de Schelpvisscherij Langs de Noordzeekust Nadeelig Kan Zijn Voor Het Weerstandsvermogen Van Het Strand en het Behoud Der Duinen als Zeewering" (1896).

encroaching on the coast. The low water line has crept landward, and the beach has become more steep. There has also been a wasting away of the foot of the sand dunes.

For the first part of the period over which the observations extend (1843–56), there appears to have been a retreat of the low water line from the shore, and consequent increase in width of the beach, in the northern portion of the coast for the first forty-four miles, and this continued up to 1866 to a less extent. After this, the low water line began to advance landwards until 1877, when the northern beach began again to grow wider, but the decrease continued along the southern half. On an average there has been a loss of beach along the whole coast between 1846 and 1894, the total average loss for the forty-six years being 155 feet for North Holland and 108 feet for South Holland. The greatest change has taken place between the Helder and Petten, a distance of 12 miles, the low water line having advanced landward an average of 160 feet. Near Callangstoog, where the effect of the great gale of 1894 was most felt, the low water line is from 200 to 270 feet more inland than in 1846, and the foot of the dunes has been driven back more than 300 feet.

Near Zandvoort there has been a gain of 100 to 130 feet. Near Scheveningen the low water line has approached nearer the shore, for a length of about four miles for about 200 feet, and the foot of the dunes has been scoured away to an average of 100 feet, and in one place as much as 400 feet. The dunes have also wasted, although in a less degree. From the Helder to Egmont, a distance of 25 miles, there has been an average loss of about 150 feet. From there to Ymuiden the foot of the dunes has remained about stationary; and from Ymuiden to the Hook of Holland, excluding the part at Scheveningen, there has been an average gain of about 65 feet.

Ymuiden Harbour is situated nearly in the centre of the embayment, and the piers project about a mile out from the shore. The works were commenced in 1865, and finished in 1876. Since the commencement of the piers, sand has accumulated both on the north and south sides of the harbour, and in 1894 the accumulation had extended along the north pier seaward for a distance of about 1500 feet, and along the beach for 1½ miles, this being the measure of the two sides of the triangle forming the pocket where the material had collected.

On the south side of the harbour the seaward measurement of the accumulation was at the same period 360 feet, and along the beach about 1¼ miles.

The material thus accumulated appears to be due to a transposition of material, as previous to the piers the beach was increasing at this part of the coast, and has since considerably diminished.

The accumulation at the piers, forming the entrance to the Maas, which extend seaward about a mile, has not been so great. On the north side the sand has extended seaward, since the construction of the piers in 1863–72, 820 feet, the width of the extension along the beach being 2 miles. On the south side the accumulation extends outwards 700 feet. Here also there is a corresponding diminution of the beach for some distance to the north of the piers.

In December 1894 there occurred a very heavy gale, accompanied by the highest tide on the Dutch coast recorded during the present century, and an immense amount of damage was done to the fishing fleet. Out of 200 boats moored at the foot of the sand hills near Scheveningen, not one escaped without injury, and many were entirely destroyed. The damage done to the sand dunes, on which this part of the country depends for its protection from the sea, was very extensive, and throughout nearly the whole length the foot was washed away, leaving the mounds with steep sides. The stone pitching on the Helder Sea Dyke was damaged over a surface of about 5000 square yards. In North Holland, the tide broke through the sand hills in several places, and near Callanstoog the hills were breached for a distance of 2 miles, the tide inundating the low land behind.

W. H. Wheeler.

## *RESULTS OF THE SCIENTIFIC EXPEDITION TO SOKOTRA.*

During the past winter a biological and geographical investigation of the Island of Sokotra (lying in about 12° north latitude and 54° east longitude), some 600 miles south-east of Aden, was undertaken, on behalf of the British Museum, by Mr. W. R. Ogilvie-Grant, and, on behalf of the Liverpool Corporation, by the Director of Museums (Dr. H. O. Forbes). Mr. W. Cutmore, of the Liverpool Museum, accompanied the party as taxidermist. From the *Bulletin* of the Liverpool Museums we learn that the expedition landed at Aden on November 18, 1898. Political difficulties between the Government of India and the Sultan of Sokotra unfortunately caused some delay in starting, but through the kindness of the Political Resident, Brigadier-General Creagh, V.C., these days were employed in visiting Sheik Othman and Lahej in South Arabia, where collections of considerable interest were made. On December 1, the difficulties referred to having been surmounted, the party was enabled to leave for Sokotra on board the Royal Indian Marine steamer *Elphinstone*, which had most generously been placed at its disposal by the Indian Government. Permission was also kindly given to detain the vessel for some days at Abd-el-Kuri, a previously unexplored island lying between Sokotra and Cape Guardafui, the eastern horn of Africa. There four days were spent in making as complete a collection of the fauna, flora and geology of the island as the time permitted. On December 7, the expedition was landed on Sokotra, near Hadibu, the capital, and it remained on the island till February 22, 1899. On the return voyage, a second visit was paid to Abd-el-Kuri for a couple of days, to enable more complete collections from that out-of-the-way spot to be made.

A complete account of Sokotra, with a map, a list of the collections, and full descriptions of the new species obtained by the expedition, illustrated by plates and blocks, will be published as a special volume, which is now in active preparation. Meanwhile, short diagnoses of some of the more conspicuous zoological novelties are given in the May number of the *Bulletin* of the Liverpool Museums.

Dr. Forbes reports to the Museums Sub-Committee that the share which Liverpool receives of the collections is as follows:—Of mammals, there are examples of one or two species of rat, of one species of civet cat, of one species of bat, and of the wild ass. Of birds, there are some 300 specimens, 250 in skin and 50 in spirit, out of which seven species have been diagnosed as new to science; a large series of reptiles has been acquired, which contains one genus and eight species new to herpetology. Numerous scorpions, millipedes and spiders, their exact number not yet ascertained, have been obtained, among which there turn out to be at least one new genus and seven new species; the land-shells number several thousands, of which Mr. Edgar Smith, of the British Museum, has already described eight species as new to his department of zoology. No doubt others will prove to be previously unknown. Of insects—almost the whole of which were collected by Mr. Ogilvie-Grant—there are several thousands, the majority of which have not yet been examined.

The plants, of which living specimens or ripe seeds—over 200 in number—have been brought home, are not only of the highest scientific interest, but, being at this moment unique out of Sokotra, are of great commercial value. Their cultivation is being undertaken by Prof. Bayley Balfour in the Royal Botanical Gardens, in Edinburgh. The plants, when in a condition to exhibit, will attract the keenest interest of all horticulturists by the beauty of many of them and by the bizarre form of others.

The report states that the true Sokoterians are only poorly civilised Mohămedans, living in caves or rude cyclopean huts, and possess but few utensils, implements, or ornaments, and no weapons. The ethnographical collection is consequently very small. Specimens of their pottery, of their primitive quern-like mills, of their basket work, and of their weaving apparatus were, however, obtained, and also two large blocks of stone, inscribed with an ancient script, which may perhaps throw some light on the indigenes of the island in a past age, and of whose cyclopean remains photographs were obtained.

Dr. Forbes concludes his report by pointing out that among scientific circles, especially among geographers and biologists, there has everywhere been expressed the warmest appreciation of the liberality and public-spirited action of the Liverpool Museums Committee and the City Council in taking part in the exploration of Sokotra; and also a hearty recognition of the great credit which unquestionably belongs to them of having been the first non-metropolitan Committee to recognise that it was the part of a great Corporation possessing an important scientific institution like the Liverpool Museums, not only to furnish their galleries with examples of what is already known, but also to further the advancement and increase of knowledge by actively sharing in the investigation of unknown regions.

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The 202nd meeting of the Junior Scientific Club was held on May 26. After private business, Mr. J. M. Wadmore (Trinity) read a paper on caoutchouc; Mr. M. Burr (New College) exhibited some live walking-stick insects; and Mr. H. E. Stapleton (St. John's) read a paper on Dulong and Petit's law.

---

AN exhibition of practical work executed by candidates at the recent technological and manual training examinations of the City and Guilds of London Institute will be opened by the Duke of Devonshire, at the Imperial Institute, on Friday, June 9.

THE Edinburgh correspondent of the *Lancet* states that the court of the University of Edinburgh had recently before them a report from the committee appointed to draw up a statement and appeal for funds for University purposes, in which it was stated that the funds required for the equipment of the Public Health Laboratory and for the preparation of a library catalogue had been provided, the former by the generosity of Mr. John Usher of Norton, and the latter from the munificent bequests of the late Sir William Fraser. For the library, however, funds are still urgently required. The most pressing wants are: (1) a fire-proof room for the storage of rare books of the fifteenth and early sixteenth centuries and the MSS., which number about 7000; (2) a fund, amounting at the lowest figure to 25,000*l.*, for the purchase of scientific and literary journals and of larger works of reference; and (3) extensive structural changes and new book-cases, costing at least 5000*l.*, or a new and suitable building for the library. Another direction in which it will soon be necessary to spend money is the establishment of the Physical Laboratory. The construction and equipment of this laboratory will be a large undertaking, but it is one which will have soon to be faced if the scientific reputation of the University is to be maintained.

## SCIENTIFIC SERIALS.

*American Journal of Science*, May.—Some experiments with endothermic gases, by W. G. Mixter. The endothermic gases operated upon were acetylene, cyanogen, and nitrous and nitric oxides. A beautiful experiment described is one in which acetylene is decomposed at a dull red heat. The gas issues from a narrow tube into a wider tube, heated by a Bunsen burner. When the glass begins to glow there is a slight puff, and the stream of gas issuing from the narrow tube glows, or rather the carbon particles glow in it with the heat of dissociation of the acetylene.—A hypothesis to explain the partial non-explosive combination of explosive gases and gaseous mixtures, by W. G. Mixter. Detonating gas, a mixture of carbonic oxide and oxygen, one of cyanogen and oxygen, and other explosive mixtures of gases, do not explode below certain pressures when sparked. Explosions do not occur because of the infrequency of impacts of molecules having a velocity or internal energy adequate for chemical union. Some of the molecules combine, but the heat of their union is not sufficient to restore the energy lost by radiation, and the change is therefore not self-propagating.—Occurrence of palæotrochis in volcanic rocks in Mexico, by H. S. Williams. Origin of palæotrochis, by J. S. Diller. These two papers effectually dispose of the hypothesis of the organic origin of the siliceous formations described by Emmons as due to some primordial coral. Prof. Williams describes some specimens coming from an old eroded volcanic cone made up of altered porphyry and volcanic tuffs, situated north-east of Guanajuato in the Santa Rosa mountains. A microscopical study of thin sections reveals the fact that the nodules are spherulites, a common feature of acid igneous rocks.—Association of argillaceous rocks with quartz veins in the region of Diamantina, Brazil, by O. A. Derby. Red clay is always associated with the quartz veins of the diamond region of Minas Geraes, Brazil. The author describes a remarkable layer of that kind, one to two metres thick, which has received from the miners the name of *Guia* (Guide), because, as they state, diamonds were to be looked for below the outcrop of this layer, and not above it.—Volatilisation of the iron chlorides in analysis, and the separation of the oxides of iron and aluminium, by F. A. Gooch and F. S. Havens. The fact that ferric oxide is completely volatile in HCl gas applied at once at a temperature of 500°, and at 200° if the acid carries a little chlorine, opens the way to many analytical separations of iron, notably to the separation of intermixed iron and aluminium oxides.—Preliminary note as to the cause of root pressure, by R. G. Leavitt. The author applies the latest researches on osmotic pressure to the known facts of plant physiology.

*Bulletin of the American Mathematical Society*, May.—Prof. Holgate gives an account of the April meeting, of the Chicago Section, at Evanston, April 1. There were two sessions in the day, and twelve papers were communicated.—Prof. Bôcher gives an elementary proof that Bessel's functions of the Zeroth order have an infinite number of real roots. This was read at the Society's February meeting (*cf.* Gray and Mathews' "Treatise on Bessel Functions," p. 44.) A generalisation of Appell's factorial functions (read at the December 1898 meeting), by Dr. Wilczynski, is a slight modification of Appell's proof. The writer proposes to discuss these functions more fully later on. A paper, read at the February meeting, by Prof. J. Pierpont, entitled "On the Arithmetization of Mathematics," is an attempt to show why arithmetical methods form the only sure foundation in analysis at present known. General reasons are indicated in a paper by Klein ("über Arithmetisirung der Mathematik," *Gottinger Nachrichten*, 1895). The paper enters into considerable detail. There is much metaphysics as well as mathematics.—Prof. E. W. Brown contributes an appreciatory review of Prof. Darwin's work on the tides and kindred phenomena of the solar system, and also notices "Leçons sur la théorie des Marées," by Maurice Lévy.—The Notes give an account of a projected change in the "Annals of Mathematics," which is to be inaugurated in vol. xiii., and a full list of the subjects of lectures at a dozen German universities, besides some notes of personal matters.

*Wiedemann's Annalen der Physik und Chemie*, No. 4.—Pitches of very high notes, by F. Melde. The author reviews the various methods by which very high pitches have been determined. These include subjective methods like those by direct hearing and by difference tones, and objective ones like the various vibrographs and the author's own method of resonance. The author admits that the method of difference tones is untrustworthy, and points out certain advantages of the sensitive flame which might be utilised.—Viscosity of gases, by P. Breitenbach. Of the two methods for determining the viscosity of gases, that of transpiration through a capillary tube, and that of the oscillation of a solid, the latter indicates a greater increase of viscosity in the temperature. But in any case the increase is not quite proportional to the temperature.—Effect of electric oscillations upon moist contacts, by E. Aschkinass. Two pointed copper wires which just touch each other act as an ordinary coherer in air or alcohol, but when immersed in water, or when the points are only connected by a drop of water, the action is reversed, since electric waves have the effect of temporarily increasing instead of reducing the resistance. In another form of the experiment, a few drops of water are added to the copper filings of an ordinary coherer. This reversed action is as yet entirely unexplained.—Emission and absorption of platinum black and lamp black with increasing thickness, by F. Kurlbaum. The emission of blackened surfaces is compared with that of an "absolutely black body" in the shape of an orifice of a brass vessel blackened inside and kept at a constant temperature by circulating steam. A bolometer is exposed to radiation from this orifice and to films of black substances kept at the same temperature. It appears that platinum black has a higher absorptivity and emissity at greater thicknesses, whereas that of lamp black is greater in very thin layers. Neither of these substances absorbs heat rays of great wave-lengths. For most purposes, platinum black is to be preferred, if only on account of the facility in controlling its electrolytic deposition.—Radius of molecular action, by W. Mueller-Erzbach. Films of bees-wax or sealing-wax were protected by thin layers of gum against the dissolving action of carbon bisulphide vapour. The thickness of the layer of gum required for effectively protecting sealing-wax was 0·35 mm., whereas bees-wax was sufficiently protected by a layer only 0·14 mm. thick.

THE April issue (vol. lxv. part 4) of the *Zeitschrift für Wissenschaftliche Zoologie* contains five articles, of which, perhaps, the one by Messrs. Eimer and Fickert, on the evolutionary history of the Foraminifera, is the most generally interesting.

More than one hundred pages of the journal are devoted to this subject; and the elaborate genealogical tree given on p. 464 supplies in concise form the general results of the authors' investigations. The other articles include one on the Infusoria found in the stomachs of domestic Ruminants, by A. Günther; one on the urinogenital system of certain Chelonians, by F. von Müller: a third, by J. Meisenheimer, on the morphology of the kidneys of the Pulmonate Mollusca; and a fourth, by G. Forssell, on the Lorenzinian ampullæ in the Spiny Dogfish. After describing in detail the histology of these head-organs, the author considers that further experiments must be made before their precise function can be fully determined.

## SOCIETIES AND ACADEMIES.

### London.

**Physical Society**, May 26.—Mr. T. H. Blakesley, Vice-President, in the chair.—A paper, by Prof. S. Young and Mr. Rose-Innes, on the thermal properties of normal pentane (Part 2), was read by Mr. Rose-Innes. In the first paper on this subject, read before the Physical Society last December, it was shown that the relations existing between the volume temperature and pressure of normal pentane could be closely represented by the equation

$$p = \frac{RT}{v}\left\{1 + \frac{e}{v + k - gv^{-2}}\right\} - \frac{l}{v(v+k)}.$$

This formula was first used in connection with isopentane, and it has been shown that the values of R and $l/e$ are the same for the two isomers. The authors find that if $l$ and $e$ be taken separately equal to each other, and if the constants $k$ and $g$ be calculated from experiments on normal pentane, errors of 2 per cent. occur between the calculated and experimental results. This point has been investigated both algebraically and graphically, and the supposition that these constants are separately equal has been thought incorrect. Taking the values of R, $l/e$, and $g$ as being the same in the two pentanes, the constants $l$ and $k$ have been determined, and by this means the relations between volume temperature and pressure have been represented by the formula to within 1 per cent. The authors conclude that the difference in pressure of two isomeric substances at a given volume and temperature is of the same order as the deviation from Boyle's law, and involves the second power of the density. Mr. Rose-Innes said the formula proposed was not an absolute solution of the problem, although it was the best of a large number which had been tried. It has been applied with success to Andrews' experiments on carbonic acid, and to experiments which have been made upon ether and hexane. In the latter case, the range in volume was too small to afford a rigorous test of the value of the formula. The range in volume in isopentane was from 4000 to 3·4; in normal pentane, from 300 to 3·4; and in ether, from 350 to 3·4. The temperature varied in different experiments from 40° C. to 280° C. Objections have been raised to the formula on account of the number of constants it contains and its complexity. Mr. Rose-Innes pointed out that it was necessary to have a complex formula, as they were not dealing with a simple problem, but with the results of experiments which went so far below the critical temperature that the volume occupied was only 3·4 times as great as the space which would have been occupied by the molecules at their closest packing. The reader of the paper compared the proposed formula with formulæ of Clausius, Sutherland, and Tait containing four, four, and six constants respectively, and finally with the original equation of Van der Waals applied to experimental results by Amagat. It was shown that the agreement was much closer and the range greater. Prof. Callendar expressed his interest in the wide applicability of the authors' formula, and asked if any theoretical significance could be assigned to the various constants which appeared. Mr. Rose-Innes said the R of their formula was the R of the perfect gas equation, and that the $l$ and $e$ corresponded respectively to the $\beta$ and $\alpha$ of the ordinary Van der Waals expression. So far as he knew, the $k$ and $g$ were meaningless.—A paper on the distribution of magnetic induction in a long iron bar, by Mr. C. G. Lamb, was postponed until the next meeting.

**Chemical Society**, May 18.—Prof. Thorpe, President, in the chair.—The following papers were read:—Corydaline (Part vi.), by J. J. Dobbie and A. Lauder. Corydaldine, $C_9H_7NO(OMe)_2$, an oxidation product of corydaline, is shown to be closely related to oxyhydrastinine; the so-called corydalinic acid is an acid ammonium hemipinate.—Oxidation of furfural by hydrogen peroxide, by C. F. Cross, E. J. Bevan and T. Heiberg. Furfural is oxidised by hydrogen peroxide in presence of iron salts to a hydroxyfurfural and the corresponding hydroxypyromucic acid; the hydroxyfurfural reacts with phloroglucinol and resorcinol in a similar way to the lignocelluloses. It is shown thus that a furfuralphenol is a constituent of the lignocelluloses.—Note on the reactions between sulphuric acid and the elements, by R. H. Adie.—On the action of ethylene dibromide and of trimethylene dibromide on the sodium derivative of ethylic cyanacetate, by H. C. H. Carpenter and W. H. Perkin, jun. Improved methods for preparing tri- and tetra-methylene derivatives are given. Ethylic trimethylenecyanocarboxylate (1,1), is prepared by the action of ethylene bromide on ethylic sodiocyanoacetate, and ethylic tetramethylenecyanocarboxylate (1,1), is obtained by the action of trimethylene bromide on ethylic sodiocyanoacetate; the salts are hydrolysed by cold alcoholic potash with formation of the corresponding acids.—The maximum vapour pressure of camphor, by R. W. Allen. Experimental values for the maximum pressures of camphor vapour at 0–80° are given.

**Linnean Society**, May 4.—Mr. A. D. Michael, Vice-President, in the chair.—Mr. I. H. Burkill exhibited specimens of a daisy (*Bellis perennis*), found at Kew, in which the ray of the outer florets was so nearly absent that these consisted of scarcely more than ovary, naked style, and stigma.—Mr. F. G. Parsons read a paper on the position of *Anomalurus* as indicated by its myology. The paper contained an account of the muscles of *Anomalurus*, and a comparison of them with those of the different suborders of rodents. From previous examination of the muscles of rodents, the author arrived at the conclusion that *Anomalurus* should be placed among the Sciuromorpha, but that it had certain Myomorphine tendencies. He contrasted its muscles with those of *Pedetes caffer*, but found little reason to regard these two animals as nearly related.—Mr. George Murray, F.R.S., on behalf of Miss Ethel S. Barton, communicated a paper on *Notheia anomala*, an obscure species of parasitic Alga, and described its mode of growth and reproduction, some remarks being made by Mr. W. Carruthers, F.R.S.—A paper by Mr. George West on variation in Desmids was read. The Desmidieæ was shown to be morphologically specialised and to exhibit a marked pattern and symmetry of form, major and minor symmetries being recognisable in many species. Variations in form and symmetry were specially dealt with, and a summary given of all that is known concerning the variation in the cell-contents and in the conjugation of these plants. Observations were also made on the variability of the pyrenoids and moving corpuscles in the genus *Closterium*.

**Geological Society**, May 10.—W. Whitaker, F.R.S., President, in the chair.—The geology of the Davos district, by A. Vaughan Jennings. Alpine geology has attracted many workers since the date of Prof. Theobald's classic memoir on the district of which Davos forms part, and new principles of interpretation have been established. The author has more especially studied (*a*) the age of certain rocks formerly classed as "Bündner Schiefer," but distinct from the grey shales variously regarded as of Jurassic or Tertiary age; (*b*) the origin and date of the serpentine near the Davoser See; and (*c*) the tectonic structure of the district. The author discusses at length the physical structure of the district. The general trend of the Davos Valley is rather oblique to that of the greater rock-masses, which, however, is somewhat irregular. He shows that these (which have a general dip towards the south and east) form three great acute and rudely parallel over-folds, the westernmost being the most complicated; of this fold, the serpentine forms a part. It is more recent than the crystalline schists and the Casanna Schiefer, and is associated with the red and green schistose rocks already mentioned, in a way which he considers indicative of intrusion; but it nowhere cuts the Haupt-Dolomit. Accordingly he considers it to be later than the Verrucano, and not earlier than the middle part of the Trias. Certain crystalline breccias occur in the neighbourhood of the serpentines; these the author considers to be due to earth-movement, and he goes on to give reasons for regarding them as the equivalent of the Casanna Schiefer of other localities. There is, in his opinion, no evidence of the presence of

post-Jurassic strata such as Prof. Steinmann believes to exist.—Contributions to the geological study of County Waterford. Part 1, § i. The Lower Palæozoic bedded rocks of the coast, by F. R. Cowper Reed. This paper opens with an account of the previous publications on the geology of the district, and then goes on to describe the sections exposed along the coast at the following localities: Raheen and Newtown Head, Tramore Bay, Garrarus and Kilfarrasy, Annestown and Dunabrattin, Knockmahon, Ballydouane Bay, and Killelton Cove to Ballyvoyle. These sections expose shales and limestones with abundance of igneous rocks partly interbedded, but mainly intrusive; and the author is able to make out the following succession of rocks, tabulated in descending order: (4) Raheen Series. Mudstones, slates, felsites and tuffs, and fossiliferous shales. (3) Carrigaghalia Series. Graptolitic shales, thin flags, cherts, tuffs, and felsites. (2) Tramore Limestone Series. Divided into three stages. (1) Tramore Slates. Calcareous and argillaceous slates.

Zoological Society, May 16.—Dr. W. T. Blanford, F.R.S., Vice-President, in the chair.—The Secretary read extracts from letters received from Mr. J. S. Budgett, containing an account of the progress of his expedition to the Gambia, and announcing his proposed return in July next.—Mr. G. A. Boulenger, F.R.S., exhibited a specimen of the Bornean lizard (*Lanthanotus borneensis*), belonging to the Sarawak Museum, and remarked that it was the second example of this reptile that had reached Europe. An examination of the specimen had confirmed Mr. Boulenger's suspicion that its affinities were with the *Helodermatidae*, and that it was not, as its original describer (Steindachner) had supposed, entitled to family rank by itself.—Mr. G. E. H. Barrett-Hamilton exhibited the skins of two hares (*Lepus variabilis*), and made some remarks on the winter whitening of Mammals in connection therewith.—Mr. G. A. Boulenger, F.R.S., read an account of the fishes obtained by the Congo Free State Expedition, under Lieutenant Lemaire, in Lake Tanganyika, in 1898. Ten new species were described, of which three were made the types of new genera.—Mr. E. M. Corner read a note on the variations of the patella in the divers, grebes, and cormorants, by which the functions of the bones in these birds were explained.—A communication was read from Mr. Stanley S. Flower, containing notes on a second collection of reptiles made in the Malay Peninsula and Siam, from November 1896 to September 1898, and a list of the species recorded from those countries. The species enumerated in the paper were 221, of which one was the type of a new species, described under the name of *Typhlops floweri* by Mr. G. A. Boulenger.—A communication was read from Marquis Ivrea on the wild goats of the Ægean Islands. A series of heads and some photographs of the goats of the islands of Antimilo and Joura were exhibited, with the object of showing that the effect of a cross between *Capra aegagrus* and *C. hircus* (such as had been proved to have occurred on the former island) was not to produce an animal corresponding to *C. dorcas* (Reichenow), and that consequently the goat of Joura had not, as was generally assumed, been so produced, but was, as a matter of fact, a local variety of the wild goat, for which the name *C. aegagrus*, var. *jourensis*, was suggested. Mr. W. Cunnington read a paper on a new Brachyuran Crustacean from Lake Tanganyika, obtained by Mr. J. E. S. Moore, for which he proposed the name *Limnothelphusa maculata*. The crab, unlike its nearest allies, was wholly aquatic, and would seem to be the most primitive member of the Thelphusine group.—A paper was read by Mr. W. T. Calman on some Macrurous Crustaceans obtained by Mr. J. E. S. Moore in Lake Tanganyika. A new genus (*Limnocaridina tanganyikae*) and a new species of *Palaemon* (*P. moorei*) were described, it being pointed out that neither of them furnished any particular facts bearing on the general question of the origin of the Tanganyikan fauna.

CAMBRIDGE.

Philosophical Society, May 15.—Mr. J. Larmor, President, in the chair.—Mr. J. J. Lister exhibited specimens of *Branchipus* and *Estheria* raised from dry mud, obtained from the upper pool of Gihon near Jerusalem. The mud had been placed in water, after remaining dry for three years, and three days later the water was found to be peopled with the nauplius larvæ of these genera. Representatives of species of *Daphnia*, *Ostracoda* and *Copepoda* had subsequently appeared, probably identical with those described by Baird from the same locality (*Annals and Magazine of Natural History*, series iii. vols. iv. and viii.). It was pointed out that in *Branchipus* food travels forward towards the mouth along the groove which separates the thoracic appendages of the opposite sides; and the suggestion was offered that a similar course of the food may explain the masticatory character of the basal inner lobes of the anterior thoracic appendages of *Apus*.—Notes on the Binney collection of carboniferous plants; (2) a new type of Palæozoic plant, by A. C. Seward. The author gave a brief description of a fragment of stem from the Coal-Measures of Lancashire, which exhibits anatomical features differing from those of any known genus. The primary structure agrees in certain respects with that of *Heterangium*; but there are definite peculiarities which render advisable the institution of a new generic name. Among the more important characteristics may be mentioned the large isodiametric metaxylem tracheids, the position of the protoxylem elements and the structure and course of the leaf-traces.—On the modification and attitude of *Idolum diabolicum*, a Mantis of the kind called "floral simulators," by Mr. D. Sharp. Mantises are voracious insects with the front legs of remarkable form, suited to the capture of living insects which form the sustenance of the Mantis. Certain of these Mantises assume attitudes and make movements that cause them to resemble flowers, and they are moreover possessed of some modifications of structure and colour that are believed to strengthen the illusion caused by their attitudes. The facts as regarded *Idolum diabolicum* were stated, and from a comparison with other Mantises the conclusion was deduced that the modifications of structure are really slight, and that the attitude is the important point. In reference to the origin of the peculiarities, he concluded that, granted that the instinct of the creature caused it to assume the attitudes, the slight structural modifications might follow from simple physical causes.—On the product $J_m(x)J_n(x)$, by Mr. W. McF. Orr.

PARIS.

Academy of Sciences, May 23.—M. Van Tieghem in the chair.—On the deformation of general surfaces of the second degree, by M. Gaston Darboux.—On some new compounds of camphor with aldehydes, by M. A. Haller. In continuation of previous work on the subject, the author has studied the action of piperonal and of meta- and para-methoxybenzaldehydes on the sodium derivative of camphor, and has prepared a number of new compounds. Metamethoxybenzylidenecamphor crystallises in long needles melting at 51°–52° and is reduced by sodium amalgam to metamethoxybenzylcamphor. Paramethoxybenzylidenecamphor forms large crystals melting at 125°, and is converted by reduction into paramethoxybenzylcamphor, which crystallises in prisms melting at 71°. Piperonylidenecamphor crystallises in needles melting at 159°·5, and yields, on reduction, piperonylcamphor, which forms small white plates melting at 70°. Piperonyl piperonylate, which is formed along with piperonylidenecamphor, crystallises in needles melting at 97°.—On isothermic surfaces and the deformation of the paraboloid, by M. A. Thybaut.—On the deformation of certain surfaces related to surfaces of the second degree, by M. Tzitzeica.—On the development of a uniform branch of analytic functions, by M. Paul Painlevé.—On the calculation of divergent series by Taylor's theorem, by M. Emile Borel.—On the calculation of the maximum available force at the draw-bar of a motor, by M. A. Petot.—On the decomposition of silicates by hydrogen sulphide, by M. P. Didier. The majority of silicates, when heated in a porcelain tube at about 1400° C., are decomposed and partially converted into sulphides. In some cases, the latter are easily separated, owing to the occurrence of volatilisation or of crystallisation, or by their solubility in dilute acids; in others, the sulphides obtained are only attacked by reagents which decompose the original silicate. The reaction is always incomplete, since the silicate becomes covered with a protective layer of sulphide, and in the greater number of experiments the somewhat remarkable formation of a small quantity of sulphuric acid was noted. A portion of the silica appears to be reduced to silicon, and this is also found to occur in the action of hydrogen sulphide on silica alone.—On di-isoamylacetic acid, by M. H. Fournier. Ethylic di-isoamylmalonate, obtained by the malonic ether synthesis from isoamylic bromide, is a colourless liquid boiling at 278°–280°, and the corresponding acid crystallises in white plates melting at 147°–148°. The latter, when heated to 175°, is converted into di-isoamylacetic acid, which crystallises in white needles melting at 46°–47°, and is insoluble in water but very

soluble in organic solvents. The corresponding amide crystallises in white, silky needles melting at 115°.—Fluorine in mineral waters, by M. Charles Lepierre. It is maintained, in opposition to M. Parmentier, that minute traces of fluorides have been detected in many natural waters, and that considerable quantities —equivalent to 10 or 12 milligrammes of fluorine per litre—are present in the mineral water of Gerez (North Portugal), which is much esteemed for its efficacy in diseases of the liver.—On the genesis of the iron ores of Lorraine, by M. P. Villain. Arguments are brought forward in support of the theory that the oolitic ore of Lorraine is a littoral deposit, the mineralisation of which has been effected by the action of hot springs in the bed of an ancient sea.—On a parasitic fungus in cancerous affections, by M. J. Chevalier. The author has succeeded in isolating what appears to be a specific fungus from cancerous tumours, from the blood of patients, and from the air of hospitals. A temperature of from 28° to 35° is most favourable to its growth, but it is highly resistant, the spores not being destroyed by ten minutes' heating at 100°. The parasite exists in the form of conidia, a mycelium, or spherules, according to the stage of development and the medium employed. Its specific character is confirmed by the results of inoculation experiments, but further study will be required before the causal connection between the parasite and cancerous affections is definitely established.

## DIARY OF SOCIETIES.

*THURSDAY*, JUNE 1.

ROYAL SOCIETY, at 4.—Election of Fellows. —At 4.30 —The Parent-Rock of the Diamond in South Africa: Prof. T. G. Bonney, F.R.S.—Experimental Contributions to the Theory of Heredity. A. Telegony.—I. Introductory: Prof. J. C. Ewart, F.R.S.
ROYAL INSTITUTION, at 3.—Water Weeds: Prof. L. C. Miall, F.R.S.
LINNEAN SOCIETY, at 8.—On the High Level Plants of the Andes as illustrated by the Collections of Sir W. Martin Conway, Mr. Edward Whymper, and others: W. Botting Hemsley, F.R.S.—On some Australasian Collembola: Sir John Lubbock, Bart., F.R.S.
SOCIETY OF ARTS, at 4.30.—The Port of Calcutta: Sir Charles Cecil Stevens, K.C.S.I.
CHEMICAL SOCIETY, at 8.—The Hydrosulphides, Sulphides, and Polysulphides of Potassium and Sodium: W. Popplewell Bloxam.—On the Relative Efficiency of various Forms of Still-head for Fractional Distillation: Dr. Sydney Young, F.R.S.—The Salts of Dimethylpyrone, and the Tetravalence of Oxygen: Dr. J. N. Collie, F.R.S., and Thomas Tickle.

*FRIDAY*, JUNE 2.

GEOLOGISTS' ASSOCIATION, at 8.—The Pleistocene Deposits of the Ilford and Wanstead District: Martin A. C. Hinton.—The Pleistocene Mollusca of Ilford: A. S. Kennard and B. B. Woodward.—The Raised Beach and Rubble Drift at Aldrington, between Hove and Portslade-by-Sea, Sussex, with Notes on the Microzoa: Frederick Chapman.

*SATURDAY*, JUNE 3.

GEOLOGISTS' ASSOCIATION.—Excursion to Reigate. Directors: Miss M. C. Crosfield and Rev. Ashington Bullen.

*MONDAY*, JUNE 5.

ROYAL GEOGRAPHICAL SOCIETY, at 3.—Anniversary Meeting.
SOCIETY OF CHEMICAL INDUSTRY, at 8.—A New Method for the Analysis of Commercial Phenols: Dr. S. B. Schryver.—A Demonstration of Printing by Electricity without the aid of Rollers or Ink: Dr. S. Rideal.—Notes on Cacao Butter: Dr. J. Lewkowitsch.—The Use of Iron as the Active Element in Primary Batteries and for Electrolysing: Colonel J. Waterhouse.

*TUESDAY*, JUNE 6.

ZOOLOGICAL SOCIETY, at 8.30.—An Account of a Collection of Fishes made by Mr. R. B. N. Walker on the Gold Coast: Dr. A. Günther, F.R.S.—On a Specimen of *Cervus belgrandi*, Lart. (*C. verticornis*, Dawk.) from the Forest-Bed of East Anglia: Dr. S. F. Harmer, F.R.S.—On a Few Points in the Structure of Laborde's Shark (*Euprotomicrus labordii*, Müll. and Henle): Dr. R. O. Cunningham.

*WEDNESDAY*, JUNE 7.

GEOLOGICAL SOCIETY, at 8.—On the Geology of Northern Anglesey: C. A. Matley.—On an Intrusion of Granite into Diabase at Sorel Point (Northern Jersey): J. Parkinson.
ENTOMOLOGICAL SOCIETY, at 8.

*THURSDAY*, JUNE 8.

ROYAL SOCIETY, at 4.30.—Meeting for Discussion.—*Subject*: On Preventive Inoculation: introduced by M. Haffkine.
MATHEMATICAL SOCIETY, at 8.—On Solitary Waves, Equivoluminal and Irrotational, in an Elastic Solid: Lord Kelvin, G.C.V.O.—On Several Classes of Simple Groups: Dr. G. A. Miller.—The Transmission of Stress across a Plane of Discontinuity in an Isotropic Elastic Solid and the Potential Solutions for a Plane Boundary: Prof. J. H. Michell.—On Theta Differential Equations and Expansions: Rev. M. M. U. Wilkinson.—Finite Current Sheets: J. H. Jeans.—On a Congruence Theorem having reference to an Extensive Class of Coefficients; and on a Set of Coefficients analogous to the Eulerian Numbers: Dr. Glaisher, F.R.S.

*FRIDAY*, JUNE 9.

ROYAL ASTRONOMICAL SOCIETY at 8.
MALACOLOGICAL SOCIETY, at 8.

## BOOKS, PAMPHLET, and SERIALS RECEIVED.

BOOKS.—Handbuch der Anatomie und Vergleichenden Anatomie des Centralnervensystems der Säugetiere: Drs. E. Flatau and L. Jacobsohn, 1. (Berlin, Karger).—Annales de l'Observatoire National: d'Athènes, Tome 1 (Athènes).—The Use of Lead Compounds in Pottery: W. Burton (Simpkin).—Catalogue of the Library of the Royal Botanic Gardens, Kew (London).—The Psychology of Reasoning: Dr. A. Binet (K. Paul).—An Introduction to the Study of Materia Medica: Prof. H. G. Greenish (Churchill).—La Crime, Causes et Remèdes. C. Lombroso (Paris, Schleicher).—The Coccidæ of Ceylon: E. E. Green, 2 Parts (Dulau).—The Geography of Mammals: W. L. Sclater and Dr. P. L. Sclater (K. Paul).—Animals in Motion: E. Muybridge (Chapman).—Antiquities from the City of Benin, &c., in the British Museum: C. H. Read and O. M. Dalton (London).

PAMPHLET.—Geology of the Country around Carlisle: T. V. Holmes (London).

SERIALS.—Quarterly Journal of Microscopical Science, May (Churchill). Papers read before the Engineering Society of the School of Practical Science, Toronto, No. 12, 1898–99 (Toronto).—Agricultural Gazette of New South Wales, April (Sydney).—American Geologist, May (Ginn).—Records of the Australian Museum, Vol. 3, No. 5 (Sydney).—Proceedings of the Royal Physical Society, Session 1897–98 (Edinburgh).—Himmel und Erde, May (Berlin).—Memoirs of the Geological Survey of India, Vol 28, Part 1 (Calcutta).—Journal of Applied Microscopy, April (Rochester, N.Y.).—North American Fauna, No. 14 (Washington).—Science Gossip, June (Strand).—English Illustrated Magazine, June (Strand).—Chambers's Journal, June (Chambers).—Bulletin of the American Mathematical Society, May (New York).—Good Words, June (Isbister).—Sunday Magazine, June (Isbister).

THURSDAY, JUNE 8, 1899.

## MAN, PAST AND PRESENT.

*Man, Past and Present.* By A. H. Keane. "Cambridge Geographical Series." Pp. xii + 548, illustrated. (Cambridge University Press, 1899.)

A TRUSTWORTHY and up-to-date work in a small compass on "Ethnology" in its wider sense, in which the human race should be considered in greater detail from a zoological (anthropological) rather than from a linguistic and cultural (ethnological) point of view, was a decided want in this country. And this want has been well supplied by the volume before us, with its precursor in the same series published three years ago under the title of "Ethnology." It is, however, in our opinion, a matter for distinct regret that the author and the editor did not at first starting definitely make up their minds as to the extent to which the subject of ethnology (again using the term in its wider sense) was to figure in the series. Had this been done, a considerable amount of useless and irritating repetition might have been avoided, while the present volume would have been much more fully illustrated.

According to the present arrangement, the second part of the "Ethnology" treats of the primary divisions of mankind, of which the author recognises four; and in each of these divisions the chief groups or sections are described in more or less detail. In the present volume, on the other hand, attention is directed to the detailed classification of the various groups and races of the four main divisions. It would have been far preferable had the descriptions of the main divisions given in the first volume been immediately followed by the detailed history of the race-groups which appears in the second, with a blending of some of the matter relating to these latter from the "Ethnology," and the omission of the rest. The numerous excellent illustrations of racial types in the first volume would then have been available for the detailed descriptions in the second, where they are now so sorely needed. To illustrate what we mean, we may refer to the notices of the Andamanese on p. 256 of the first, and p. 158 of the second volume. In both instances we are informed that these people were miscalled "Mincopies," in both that their language is unlike any other, and in both that their numerals only extend to two, but that ten can be counted by means of the fingers. Again, if the accounts of the Bushmen and Hottentots on pp. 248 and 250 of the first, and p. 121 of the second volume be compared, it will be found that while there is a certain amount of repetition; neither is complete without the other, so that a judicious blending is clearly required.

But this is not quite all the fault we have to find with the general plan adopted by the author, who, we venture to suggest, would be all the better for a little training in descriptive zoology. For instance, in neither volume do we find a definite description of the characters of the Negroid division ("*Homo aethiopicus*"), as distinct from all other divisions; although in the one under consideration we have many such division-characters given as distinctive of a minor group, to wit, the Sudani negroes. Still more pronounced is this confusion in the case of the Mongoloids ("*Homo mongolicus*"), of which the division-characters are correctly given on p. 297 of the first volume, only to be repeated as group-distinctions on pp. 169 and 170 of the second. And here it may be mentioned that, since the author insists very strongly on the specific unity of mankind, he has no justification for using the names above referred to. The proper terms should, of course, be *Homo sapiens aethiopicus* and *H. s. mongolicus*.

In his treatment of the four main divisions of mankind in the present volume, the author commences with the Negroid; and his clear account of the essential difference between the Sudani and Bantu sections of African Negroes affords an important contribution to a very difficult subject, in which a considerable amount of new matter appears. It is, however, a matter for regret that the author has seen fit to discard M. Hamy's convenient term "Negrillos" for the dwarf races of equatorial Africa, since if they are called Negritos, it is liable to lead to confusion with the Andamanese and other Oceanic Negroid races. In treating of the southern Bantu, the author draws attention to the fact that the term Kaffir is only a corruption of the name Kafir applied indiscriminately by Muhammedans to all unbelievers, as exemplified by the Siahposh Kafirs of Central Asia. He consequently suggests the substitution of "Zulu-Xosas" for Zulus and Kaffirs; but unless, which is extremely unlikely, this meets with popular acceptation, the proposed change does not seem advantageous. Mr. Keane fully supports Sir Harry Johnston's estimate of the non-progressive nature of the Negro character (even in its Bantu modification); and he accordingly agrees with Mr. Bent in regarding the Zimbabwe ruins as of Arabic origin.

In the classification of the oceanic members of the Negroid group, the author follows the generally received views. He, however, considers that the Papuans, although nearly allied to Melanesians, should not be merged in the latter, and therefore proposes the term Papuasians for the two. On p. 145 he states that

"the ethnological parting-line between the Malayan and Papuasian races, as first laid down by Wallace, nearly coincides with his division between the Indo-Malayan and Austro-Malayan floras and faunas, the chief differences being the position of Sumbawa and Celebes. Both of these islands are excluded from the Papuasian realm, but included in the Austro-Malayan zoological and botanical regions."

In this connection it is unfortunate that Mr. Keane does not appear to have seen certain recent works, in which the right of Celebes to be included in the Orienta region is very strongly urged. Had he done so, he would have been able to point out an interesting coincidence between ethnographic and zoological boundaries.

Evidence in favour of another such coincidence is noticeable in the author's contention that Tibet is the cradle of the Mongol division of mankind, the mammals of that plateau being, as is well known, curiously different from those of adjacent districts. As Tibet slowly rose from a lower elevation in Pleistocene times, so, if we understand the author rightly, the Mongols gradually became differentiated from a more generalised human stock, subsequently to descend and pour over the lowlands to the south.

It seems partly due to this hypothesis that the author is strongly in favour of regarding the native races of America as entitled to form a distinct primary division of mankind, and not a part of the Mongoloid. He states, however ("Ethnology," p. 336), that "the American undoubtedly approximates nearest to the Mongol form, and as the latter cannot be derived from the former, it follows, as is now generally allowed, that the American type has been differentiated from a generalised Mongol prototype." This is really a distinction without a difference; and as we scarcely suppose that any anthropologist would derive Americans from the typical Mongol as we know him now, there seems little reason for departing from the view that the former are a branch of the Mongoloid division.

Even, however, in his own view, the author does not appear quite logical, for, after speaking of the above-mentioned close relationship of Americans and Mongols, on p. 353 of the present volume, he seeks to connect the Eskimo with the long-headed palæolithic man of Europe. Now, Sir William Flower, in his address to the Anthropological Institute in 1885, stated that "such scanty remains as have yet been discovered of the early inhabitants of Europe present no structural affinities to the Eskimo, although it is not unlikely that similar external conditions may have led them to adopt similar modes of life." This very definite statement requires refutation before the opposite view can be maintained; and then it has to be shown that the palæolithic long-head approximated to a Mongoloid type. Moreover, if he should be so proved, then he must apparently have been near to, if not the actual progenitor of, the typical Tibetan Mongol; and if so, how can the Eskimo and the Mongol be genetically separated?

In one other important point Mr. Keane also departs widely from the classification adopted by Sir William Flower. This is in regard to the peoples commonly called Polynesians, or Eastern Polynesians. These, which include the Samoans, Maori, Tongans, Tahitians, Marquesas Islanders, and Hawaians, together with some of the Fijians, are regarded by Sir William as an offshoot from the Mongolian stock, displaying evidence of a Melanesian crossing. Their resemblance to the Caucasic type has, writes Sir William,

"led some writers to infer a real extension of the Caucasian element at some very early period into the Pacific Islands, and to look upon their inhabitants as the product of a mingling of all three great types of men. Though this is a very plausible theory, it rests on little actual proof, as the combination of Mongolo-Malayan and Melanesian characters in different degrees, together with the local variations certain to arise in communities so isolated from each other and exposed to such varied conditions as the inhabitants of the Pacific Islands, would probably account for all the modifications observed among them."

This "very plausible theory" is adopted in its entirety by Mr. Keane; and, under the name of "Indonesians," we find the Polynesians on p. 562 of the volume before us definitely taking their place in the Caucasian division; the remark being added, that "their claim to belong to this connection can no longer be seriously questioned." In view of the passage quoted above, this statement appears to us decidedly too positive to be employed in a controversial case of this description. It is noteworthy that in the "Ethnology" these same "Indonesians," though considered of Caucasian origin, are still retained in the chapter devoted to Mongolians.

It may be added that in both volumes the amount of space devoted to the Polynesians is far too short, the Maori especially having only a very few lines assigned to them. Little is also said with regard to the Melanesians of Fiji; and we have been unable to discover a reference to the remarkable dolichocephalic development of the Kai Colo mountain tribes of those islands.

Further criticism is prevented by lack of space. We may accordingly conclude by the expression of our sense of the high value of Mr. Keane's work, which will be acceptable alike to the advanced student of ethnology and to all those interested in the natural history of their own race. The issue of a second edition of the "Ethnology" sufficiently vouches for the popularity of that volume. Should a new edition of both volumes be called for, we venture to think that if the author could see his way to combine and amalgamate them on the lines suggested above, a very admirable work would be presented in a form more convenient for general reference.

R. L.

## *PRACTICAL GEOMETRY.*

*Text-book of Practical Solid Geometry, &c., for the use of the Royal Military Academy, Woolwich.* By Captain E. H. de V. Atkinson, R.E. Pp. 116 + xvi plates. (London: E. and F. N. Spon, Ltd., 1899.)

*Geometrical Drawing for Army and Navy Candidates and Public School Classes.* By E. C. Plant, C.B. Vol. I. Practical Plane Geometry. Pp. xiv + 186. (London: Macmillan and Co., Ltd., 1899.)

THE characteristic deficiencies of English text-books are painfully conspicuous in most of the current works on practical geometry. Take a second-rate cookery-book, and shuffle the recipes at random; you will have a fair analogy to the quality and sequence of the books provided for the Army cadet or the Science and Art candidate. Assuredly they manage these things better in France. A century ago, Monge expounded the principles of the method of plan and elevation (*géométrie descriptive* as he called it) with a simplicity, clearness and order which have never been surpassed, although, no doubt, improvements in detail have been effected. The school which Monge created followed loyally in the steps of their master; and the consequence is that in France a student of civil or military engineering can attend a course or study a treatise on descriptive geometry which makes him familiar with a *method*, a system of elementary principles which he can apply to an endless variety of practical problems.

"Monge a souvent répété que, lorsqu'on savait les divers problèmes relatifs au point, à la droite et au plan, et dont l'ensemble forme ce que l'on appelle encore et assez improprement *les préliminaires de la géométrie descriptive*, on savait la géométrie descriptive."

So says Olivier in the preface to his excellent course published in 1843-4, and based upon lectures actually delivered in the École Centrale des Arts et Manufactures.

Accordingly, after a brief introduction, M. Olivier discusses the representation of the point, the straight line, and the plane, and the elementary problems relating to them. What is offered instead of this to the English student? Rules for finding the plan and elevation of an equilateral triangle, of a cube, octahedron, &c., in various specified positions, with a very few really fundamental problems apologetically inserted here and there. Now although the representation of a few concrete solids may be useful to help the beginner to see the object of orthogonal projection, a text-book wholly, or almost wholly, devoted to such special problems is of very little use, except for the passing of examinations set exclusively on these lines.

Similar remarks might be justly applied to most of our books on practical plane geometry and perspective. The almost invariable rule is to give a more or less numerous set of isolated examples, all worked out, with as little discussion of principles as possible: the result is that the student, instead of being provided with a powerful instrument capable of endless adaptation, is merely acquainted with a bundle of dry practical rules.

The works which have suggested these observations are by no means the worst of their class: on the contrary, they are much better than the average, and mark, it is to be hoped, a movement in the direction of reform.

Captain Atkinson's book is intended chiefly for the Royal Military Academy, and its scope has doubtless been dictated by this consideration. Its principal merit is that it contains three chapters on horizontal projection (*i.e.* the method of an indexed plan) which really do give a useful and practical outline of this method in an orderly way. Most of the elementary problems are solved, and the examples appear to be well chosen. It would have been a good plan to give the data of some unworked problems graphically instead of stating them all in words. The earlier part of the book is less attractive; it contains a bare outline of orthogonal projection and a few miscellaneous notes on regular solids, ways of drawing an ellipse, &c. The book ends with a sketch of the method of isometric projection. The plates are clear: unfortunately they are printed on folded sheets, and bound up at the end of the book; this makes it very difficult to follow a figure and the text relating to it simultaneously. If the plates were bound separately the convenience of the work would be greatly increased.

Mr. Plant discusses a great variety of problems, which have been arranged in groups in a fairly systematic way. The figures are from photographs of actual drawings by the author and his assistants, and so afford the student a real practical standard of accuracy. The book is likely to be very useful to the classes for whom it is intended: at the same time, there are several points on which it appears to us rather open to criticism.

In the first place, the attention given to different groups of problems is not proportional to their importance. At least half of the problems in sections G to K might have been set as exercises; this would have given space for a discussion of similar figures—an important subject almost ignored.

Again, the use of set squares for drawing parallels receives no attention, although these instruments are casually mentioned in the introduction. Nothing is more essential to the draftsman than familiarity with the use of set squares; compass constructions (such as those given in this book) for drawing parallels and perpendiculars are seldom used in practical work.

In a similar way, the use of the protractor for setting off angles is not sufficiently brought out. There is actually a section on the construction of certain special angles (such as $67^{\circ}\ 30'$) without a protractor. The section on regular polygons is specially unsatisfactory: there may be some sense in giving an accurate compass construction for a pentagon, but what earthly use is there in giving *incorrect* constructions (*e.g.* for the heptagon, p. 30 and elsewhere) which only afford an approximation obtainable much more simply by means of a protractor or scale of chords, or even by a method of trial? It may be added that these approximate constructions are given without any warning of their real inaccuracy.

Finally, there are a good many examples of no practical importance: for instance, group J is "To inscribe a square in all (!) the figures capable of containing it." Of course when questions of this kind turn up as Euclid riders, it is a good thing to make a schoolboy draw an accurate figure; but to include them in a text-book of practical geometry is waste of space.

The fact is that ideal treatises on practical geometry in all its branches, for the use of English students, have yet to be written. Ordinary plane geometry, orthogonal projection, perspective and projective geometry—all these are methods of extreme value, both to the mathematician and to the engineer, when they are really mastered; but a mere smattering is of very little use. Unless you know thoroughly the elementary principles involved, the solution of hundreds of isolated examples is little better than waste of time: here, as elsewhere, an ounce of theory is worth a ton of "practice" of the usual kind. Real practice, of course, is indispensable; but it should be systematic, and illustrate principles of general application. G. B. M.

## OUR BOOK SHELF.

*Michael Faraday: His Life and Work.* By Silvanus P. Thompson, D.Sc., F.R.S. Pp. ix + 308. "The Century Science Series." (London: Cassell and Co., Ltd., 1898.)

THE lives of men to whose genius and untiring devotion to research the stately edifice of modern science owes its existence, have a fascination and an interest which appeal to a much wider circle than that of the few who are able to realise the full significance of their epoch-making scientific discoveries. Even those to whom science is little more than a name are capable of feeling a keen interest in everything that concerns the purely human element in the lives of the great leaders in science. Hence there has arisen a demand for biographical literature of this type, a demand which the "Century Science Series," to which the volume before us is the latest addition, is intended to meet.

Of all the great names in the history of science which have become household words in civilised communities, that of Michael Faraday will always stand out pre-eminently as that of one in whom genius was wedded to a childlike simplicity and transparent sincerity of character but seldom found in association with such remarkable

powers of the intellect. Faraday's career was a truly remarkable one, judged from almost every point of view. Deprived of all the advantages of a careful training in early life, and commencing the study of science at an age when the deficiencies of early education are not easily remedied, he yet, by strenuous effort and single-minded devotion to a high ideal, succeeded in working his way to the very front rank of the scientific workers of his day. Again, although in his time electrical theory was being largely developed by the great French mathematicians, and mathematical analysis was regarded as an indispensible instrument of research, Faraday, without the use of a single symbol, succeeded in discovering those great fundamental facts on which the whole structure of modern electrical engineering rests, and in determining their exact quantitative relations; he further succeeded in explaining many obscure phenomena which had eluded the grasp of the great continental mathematicians. As Clerk Maxwell discovered, he was no mathematician, yet achieved results apparently only attainable by such methods.

In the small volume before us the account of Faraday's researches is admirably rendered, and is presented in a connected manner, which enables the reader to follow the trains of thought that suggested to Faraday many of his experiments. Of peculiar interest are those negative results which must now be regarded as dim foreshadowings of later discoveries—such as the attempt to discover whether a magnetic field had any effect on the refrangibility of light when applied to its source.

But interesting as is the account of Faraday's researches to those with a moderate knowledge of physics, the general reader will probably prefer to confine his attention to the earlier and later chapters in the book, in which Faraday is presented to us from the purely human standpoint. The extracts from his letters—some of which now appear for the first time—give us interesting glimpses of his inner life. His warm human sympathies, his delight in the beauties of nature, his deep and life-long attachment to his wife, his sturdy adhesion to the religious sect in which he had grown up, his relations to illustrious contemporaries—are all topics full of interest to the general reader; and they are handled in a manner well calculated to rivet his attention and enlist his sympathy. We congratulate Prof. S. P. Thompson on having successfully brought out and emphasised the quaker-like simplicity of Faraday's character, and the remarkable freedom from complexity in which he kept his life, notwithstanding the height of his fame.

*Untersuchungen über Strukturen.* By O. Bütschli. Pp. viii + 411; Atlas to ditto; Plates 27. (Leipzig: W. Engelmann, 1898.)

IN this work the author sets forth in great detail the results of investigations, extending over six years, upon the minute structure of various bodies, products, for the most part, of the activity of living organisms. The object of these researches was to extend, and to put to the test, certain conclusions reached by the author in 1892, in his well-known work on the structure and physical constitution of protoplasm. In an appendix to the work in question he gave an account of some observations upon the minute structure of certain substances, such as gelatine and egg albumen, which exhibit the phenomena of swelling or of coagulation, and came to the conclusion that these substances possessed a minute structure which was finely honeycombed or alveolar ("Wabig"). In the present work these observations are renewed and greatly extended, both as regards minuteness of detail and in the variety of material. Besides researches upon gelatinous and coagulable substances such as gelatine, celloidin, albumen, and so forth, the author has studied the minute structure of various sphærocrystals, of natural and artificial cellulose structures, of starch granules, and finally of a number of natural products of animal tissues, such as chitin envelopes, spongin fibres, matrix of hyaline cartilage, and other similar structures.

To give an adequate account of these exhaustive researches, which cover more than 400 pages in the setting forth, is impossible in a short space; and it is to be regretted that the author has not anywhere given for the benefit of his readers a general summary or review of the results obtained by him. The book is, in fact, a collection of separate investigations, of which preliminary accounts have already appeared during the past seven years, bound up with an introduction and two discussions. In the introduction, the author gives an account of the order and sequence of his researches, and describes his methods of investigation, especially with regard to the technique of micro-photography. The two discussions deal with the question of the reality of the structural images obtained with the highest magnifications, and with certain phenomena of polarisation. On the other hand, the many interesting and important results obtained by the author have to be sifted out by the reader from a great mass of facts and arguments, which is no easy matter for those not specially conversant with the subject. It may be briefly stated, however, that in all the substances investigated Bütschli finds a distinct alveolar structure, which in the case of coagulable bodies is of the nature of a true foam ("Schaumig-wabig"), but which in crystallisable or sphæro-crystalline bodies is composed of an aggregation of minute globulites ("Globulitisch-wabig"). Amongst the many interesting facts which the author brings forward, attention may be specially drawn to his observations upon colloids, which when fixed in a state of tension develop appearances very similar to those seen in karyokinetic figures, suggesting the conclusion that the nuclear spindle is an expression of the effects of tension, rather than of actual differences of material between filar and interfilar substance. The author's results are supported by an atlas containing twenty-seven plates of beautifully executed micro-photographs, as well as by numerous figures in the text. All those who are interested in this very important field of investigation, to which Bütschli has devoted so many years of patient and laborious research, will welcome the appearance of this work, constituting as it does a solid contribution of facts which cannot lightly be brushed aside by those who may be opposed to his theories. E. A. M.

*A Manual of Library Cataloguing.* By J. Henry Quinn, Librarian Chelsea Public Libraries. Pp. 164. (London: Library Supply Company, 1899.)

THIS book is in several respects favourably distinguished from others of its class that have recently seen the light. The animosities of the library world are not imported into its pages, and in several ways the writer deprecates the subordination of practical common sense to a display of learning. He does not, for instance, condemn the unfortunate reader in search of the works of George Sand to remember that her real name was Dudevant, and to look under that heading. The book is avowedly not designed for workers in a learned institution, but is most admirably adapted for those engaged in cataloguing the contents of an ordinary library. Mr. Quinn's rules are set forth with singular clearness, and endowed with a wise elasticity. He is on the whole in favour of the "dictionary" system, wherein each book may be found, under a single alphabetical arrangement, under its title, the name of its author, and the particular portion of human knowledge with which it deals, but he also gives an adequate account of the system of "classified catalogues." An appendix gives most valuable help to the librarian in his dealings with the printer of his catalogue, and gives completeness to a most valuable little work.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### Strawberry Cure for Gout.

THE season of strawberries is at hand, but doctors are full of fads, and for the most part forbid them to the gouty. Let me put heart into those unfortunate persons to withstand a cruel medical tyranny by quoting the experience of the great Linnæus. It will be found in the biographical notes, written by himself in excellent dog-latin, and published in the Life of him by Dr. H. Stoever, translated from German into English by Joseph Trapp, 1794. Linnæus describes the goutiness of his constitution in p. 416 (*cf.* p. 415), and says that in 1750 he was attacked so severely by sciatica that he could hardly make his way home. The pain kept him awake during a whole week. He asked for opium, but a friend dissuaded it. Then his wife suggested, "Won't you eat strawberries?" It was the season for them. Linnæus, in the spirit of an experimental philosopher, replied, "*tentabo*—I will make the trial." He did so, and quickly fell into a sweet sleep that lasted two hours, and when he awoke the pain had sensibly diminished. He asked whether any strawberries were left: there were some, and he eat them all. Then he slept right away till morning. On the next day he devoured as many strawberries as he could, and on the subsequent morning the pain was wholly gone, and he was able to leave his bed. Gouty pains returned at the same date in the next year, but were again wholly driven off by the delicious fruit; similarly in the third year. Linnæus died soon after, so the experiment ceased.

What lucrative schemes are suggested by this narrative. Why should gouty persons drink nasty waters, at stuffy foreign Spas, when strawberry gardens abound in England? Let enthusiastic young doctors throw heart and soul into the new system. Let a company be run to build a Curhaus in Kent, and let them offer me board and lodging gratis in return for my valuable hints.

F. G.

### Distant Sounds.

WHEN the Prince of Wales reviewed great squadrons at the Jubilee review, only one gentleman from Wimbledon, and myself, recorded hearing the salutes near London. I think it worth while, therefore, to note that what seemed to be the thumping sound of heavy guns was to be heard here to-day, from half-past five to a quarter to six p.m., Greenwich time; and even *felt* in the chest.

Some of your other correspondents may be able to tell where the guns—if guns—were fired. The importance of the subject seems to require no remark from me.

I sit in a one-storied building, as far remote from street noises, perhaps, as is possible in London, except in one or two great private gardens, or in the parks. No road is within fifty feet of me; and I know all my neighbours' noises, and have been used to the sound of old-fashioned guns up to 1894.

W. F. SINCLAIR.

102 Cheyne Walk, Chelsea, London, S.W., June 2.

## THE JUBILEE OF SIR GEORGE GABRIEL STOKES.

THE close of the present Easter term coincides with the end of the fiftieth year of the tenure by Sir George Gabriel Stokes of the Lucasian Professorship at Cambridge. Born in 1819, the same year as our Sovereign, he entered Pembroke College the year of Queen Victoria's Accession. In 1841 he took his degree as Senior Wrangler, the earliest of the wonderful group of Cambridge mathematicians—Stokes, Cayley, Adams—who occupied that position in three successive years. It has been one of the most pleasing features of the recent jubilee that Mr. H. Cadman Jones, who was second to Stokes both in the Mathematical Tripos and in the contest for the Smith's Prize, has been able to come to Cambridge to offer his congratulations to his old friend and competitor.

In the long history of the University several chairs have been held by the same professor for more than fifty years. Prof. R. Plumtre, of Queens', was Regius Professor of Physic from 1741 to 1793; Thomas Martyn, of Sidney Sussex, was Professor of Botany from 1761 to 1825; and Adam Sedgwick held the Woodwardian Chair of Geology from 1818 to 1873; but this is the first time in the history of the University that the occasion has been officially celebrated.

In the course of his long life Sir George Stokes has been first Secretary and later President of the Royal Society. He presided over the British Association in 1869. He represented the University in Parliament from 1887 to the dissolution in 1891, and was created a baronet in 1889. He has received the Rumford and the Copley medal from the Royal Society, and is a D.C.L. of Oxford, a LL.D. of Cambridge, Edinburgh and Dublin, and a ScD. of Cambridge. Amongst the numerous honours which have been showered upon him from abroad, he is a Knight of the Prussian order "Pour le Mérite," a distinction he shares with but four or five at most of his countrymen.

This is not the place to enumerate or appreciate the vast volume of published work which Prof. Stokes has produced within the last fifty years. A quarter of a century ago one of his most distinguished pupils, Prof. Tait, attempted in these pages to give some account of the magnificent series of papers we owe to Sir George. The portrait which accompanied Prof. Tait's article is still strikingly like the original; it seems strange that five-and-twenty years should have left so little trace in those finely-moulded features.

The celebration of the jubilee commenced with the delivery of the Rede Lecture by Prof. Cornu, of the École Polytechnique of Paris. The subject of the lecture was "The Wave Theory of Light, its Influence on Modern Physics." The endowment of this lecture was left to the University as long ago as 1524 by Sir Robert Rede, Lord Chief Justice in Henry VIII.'s reign, and this is the first time that it has been delivered by a foreigner. Prof. Cornu spoke in French, and both the brilliancy of his matter and the charm of his elocution made a deep impression on his audience. Prof. Cornu, in mentioning the works of Newton, Young, Clerk Maxwell, Rayleigh, Kelvin and Stokes, paid a splendid tribute to those mathematical studies which have ever been the chief glory of Cambridge.

Sir George Stokes's College, Pembroke, entertained a distinguished company at dinner on Thursday evening. The delegates from the various Universities and learned Societies were present, and many of the former members of the Society assembled to do honour to their most distinguished graduate. As it was necessary for the company to adjourn at nine o'clock to the Fitzwilliam Museum, there were no speeches, but the health of Sir George was drunk amidst a scene of rare enthusiasm.

The Fitzwilliam Museum is admirably adapted for the purposes of an evening reception. Lit up by electric light, the walls of its spacious galleries hung with pictures, and its floor covered with a crowd dressed in the robes of the various institutions that had sent delegates, it presented a most brilliant spectacle. The guests were received by the Vice-Chancellor, supported by his Esquire Bedells. During the course of the evening a bust of Sir George Stokes, executed by Mr. W. Hamo Thornycroft, was presented to Pembroke College, and a replica was at the same time given to the University. Lord Kelvin, on behalf of the subscribers, presented the busts, and in doing so he remarked that the assembly was taking part in the celebration of a great man and of natural philosophy in the University of Cambridge—natural philosophy in the broadest sense of the term, of which foundations had been laid by Sir George Stokes that would render the nineteenth century memorable in future

centuries. Sir George Stokes commenced as an undergraduate in Pembroke College: his first experimental work was made when he was a junior Fellow. He (Lord Kelvin) well remembered that in Pembroke College there were no physical laboratories, and the first physical laboratory in European Universities, he believed—certainly in these islands—was in Sir George Stokes's rooms, which he occupied as a junior Fellow about the year 1840 to 1843. If they considered the condition of natural philosophy in 1840 and in the present year, they might form some idea of how vast had been the results of his labours. Lord Kelvin pointed out that Sir George Stokes had the courage and spirit to take up subjects absolutely beyond the range of all the mathematicians of his age. Sound, light, elasticity, mathematical problems on the one hand, properties of matter on the other, were his studies, and the results had been of splendid benefit to the world of science. To him was due the credit for having published in lectures, if not in print, the grand theory of spectrum analysis. But his published papers contained but a small part of the work he had done for science. All workers in science in the University of Cambridge, all the communicators of papers to the Royal Society during the thirty years he was Secretary and the five years he was President, would agree with him in saying that Sir George Stokes had published in his own name but a very small part of the good he had done to the world. There was a debt of gratitude due to him, not only for what he had published, but for what he had done for others. He had published papers, and the discoveries contained therein had produced a monument more enduring than marble. But, still, they would like to have a marble monument, a tangible and visible sign for the men who knew him and the work he had done; and, therefore, it was a great privilege indeed to be allowed to unveil the two busts, one designed for the University of Cambridge and the other for Pembroke College.

The busts were received by the Vice-Chancellor on behalf of the University and—in the absence, through ill-health, of the Master—by the Rev. C. H. Prior, Senior Tutor of Pembroke, on behalf of the College. We are informed that Mr. Hamo Thornycroft will undertake the production of bronze copies of his bust of Sir George Stokes, about one-third of the size of the original, at a cost of seven guineas each, in case more than twenty-five are ordered. Names will be received by Sir William Crookes, 7 Kensington Park Gardens, W., and by Prof. Perry, Royal College of Science, S.W.

On Friday, June 2, the more important functions of the jubilee took place. At 11 a.m. the delegates were received by the Vice-Chancellor in the Senate House, and in the chronological order of the foundation of the institutions they represented, they tendered their addresses of congratulation to Sir George Stokes. The name of each delegate and of the institution he represented was announced by Mr. J. W. Clark, the Registrary. The delegate then advanced and presented his address to the Vice-Chancellor, who handed it to Sir George Stokes. At the close of the presentation Sir George, in a short speech, said he often thought in reviewing a long life that he might have worked harder, and he attributed his longevity to his "comparative idleness," a sentiment which found considerable favour with the undergraduates in the gallery.

The presentation commenced with the delegates from the University of Paris, and the following is a list of the institutions represented and of those chosen to represent them:—

University of France—Prof. Gaston Darboux, Doyen de la Faculté des Sciences.

University of Oxford—Sir William Reynell Anson, Bart., M.P., and Robert Edward Baynes, M.A., Lee's Reader in Physics.

University of St. Andrews—P. R. Scott Lang, M.A., Regius Professor of Mathematics.

University of Glasgow—Very Rev. Robert Herbert Story, D.D., Principal, and Lord Kelvin, M.A., Hon. LL.D., G.C.V.O.

University of Aberdeen—Sir William Duguid Geddes, LL.D., Principal.

University of Edinburgh—George Chrystal, M.A, Professor of Mathematics, and G. F. Armstrong, M.A., Professor of Engineering.

University of Dublin—George Salmon, D.D., Provost, and Benjamin Williamson, M.A., D.Sc.

Royal Society—Lord Lister, Hon. LL.D., President; Alfred Bray Kempe, M.A., Treasurer; Michael Foster, M.A., Professor of Physiology; Arthur William Rücker, M.A. (Oxon.), Professor of Physics, Royal College of Science, Secretaries.

Académie des Sciences, Paris—Prof. Becquerel.

Königliche Akademie der Wissenschaften, Berlin—Friedrich Kohlrausch, Director of the Physikalisch Technische Reichsanstalt, Charlottenburg.

Gesellschaft der Wissenschaften zu Göttingen—Edward Riecke, Professor of Physics.

New York, Columbia University—Robert S. Woodward, Ph.D., Professor of Mechanics and Mathematical Physics, Dean of the Faculty of Pure Science.

Princeton University, New Jersey—Prof. Edgar Odele Lovett.

Bataafsch Genootschap voor Physika, Rotterdam—Dr. Elie van Rijckevorsel.

Académie Royale des Sciences des Lettres et des Beaux Arts de Belgique—Prof. Alphonse Rénard, Prof. G. Van der Mensbrugghe.

Manchester Literary and Philosophical Society—Reginald Felix Gwyther, M.A., Sen. Sec.

Royal Irish Academy—Earl of Rosse, K.P., President, George F. FitzGerald, M.A., Professor of Natural and Experimental Philosophy, Trinity College, Dublin.

Royal Society of Edinburgh—Lord Kelvin, M.A., Hon. LL.D., President, and Sir John Murray, K.C.B., Hon. Sc.D.

St. Edmund's College, Ware—Right Rev. J. L. Patterson, M.A. (Oxon.), Titular Bishop of Emmaus.

École Polytechnique—Prof. Cornu and Prof. Becquerel.

École Normale Supérieure—Mons. Borel, Professor of Mechanics and Astronomy.

Royal Institution—Sir J. Crichton Browne, M.D. (Edinb.), Treasurer.

Philosophical Society of Glasgow—Lord Blythswood.

Cambridge Philosophical Society—Joseph Larmor, M.A., President.

Royal Astronomical Society—George Howard Darwin, M.A., Plumian Professor of Astronomy, President.

McGill University, Montreal—Lord Strathcona and Mount Royal, Hon. LL.D., G.C.M.G., High Commissioner in Great Britain of the Dominion of Canada, Henry Taylor Bovey, M.A., Professor of Engineering.

University of Toronto—R. Ramsay Wright, M.A., B.Sc., Professor of Biology.

St. David's College, Lampeter—A. W. Scott, M.A., Trinity College (Dubl.), Professor of Physical Science and Mathematics.

Institution of Civil Engineers—William Henry Preece, C.B., President.

King's College, London—Archibald Robertson, D.D. (Durham), Principal.

British Association—Sir William Crookes, President.

University of Durham—Ralph Allen Sampson, M.A., Professor of Mathematics.

Cambridge Ray Club—Alfred Newton, M.A., Professor of Zoology and Comparative Anatomy.

London Chemical Society—Dr. T. E. Thorpe.

Queen's College, Belfast—Thomas Hamilton, D.D., President.

Queen's College, Galway—Alexander Anderson, M.A., President.

University of Sydney—Philip Sydney Jones, M.D. (Lond.), Fellow of the Senate of the University of Sydney.

Royal College of Science, London—John Wesley Judd, C.B. LL.D., Dean; W. A. Tilden, Professor of Chemistry.

The Owens College, Manchester—Alfred Hopkinson, Q.C., M.A., Principal.

Royal Academies of Sciences of Amsterdam—J. D. van der Waals, Professor of Experimental Physics.

University of Bombay—Dr. H. M. Birdwood, M.A., C.S.I.
University of Calcutta—Hon. J. O'Kinealy, M.A , Judge of H.M.'s High Court of Bengal.
University of Madras—Hon. H. H. Shephard, M.A., Puisne Judge of the High Court of Madras.
London Mathematical Society—Lord Kelvin, M.A., Hon. LL.D., President.
University of Tokio, Keishiro Matsui, Chargé d'Affaires, Japanese Legation, London.
University of New Zealand—Edward John Routh, M.A., Sc.D.
Durham College of Science, Newcastle-on-Tyne—Henry Palin Gurney, M.A., Principal.
University of Adelaide—Horace Lamb, M.A., Professor of Mathematics in Owens College, Manchester.
University College of Wales, Aberystwyth—Robert Davies Roberts, M.A.
Yorkshire College, Leeds—Leonard J. Rogers, M.A., Professor of Mathematics.
Physical Society of London—Oliver J. Lodge, D.Sc., Professor of Physics, University College, Liverpool, President.
Mason College, Birmingham—John Henry Poynting, Sc.D., Professor of Physics.
Baltimore (Johns Hopkins)—Simon Newcomb, Hon. Sc.D., LL.D., Professor of Mathematics and Astronomy; and Professor Ames.
Firth College, Sheffield—William Mitchinson Hicks, Sc.D., Principal.
University College, Bristol—Frank R. Barrell, M.A., Professor of Mathematics.
City and Guilds of London Institute for Advancement of Technical Education—Sir Frederick Abel, Bart.
University College, Dundee—John Yule Mackay, Principal.
University College, Nottingham—John Elliotson Symes, M.A., Principal.
Victoria University—Nathan Bodington, Litt.D., Vice Chancellor.
Royal University of Ireland—Right Rev. Monsignor Molloy, D.D., D.Sc.
Royal College of Science for Ireland—Walter Noël Hartley, Professor of Chemistry.
University College, Liverpool—Richard Tetley Glazebrook, M.A., Principal.
University of the Punjab—Sir Charles Arthur Roe, M.A., late First Judge of the Chief Court, Punjab; late Vice-Chancellor of the University.
University College of South Wales, Cardiff—H. W. Lloyd Tanner, M.A. (Oxon.), Professor of Mathematics.
University College of North Wales, Bangor—Henry R. Reichel, M.A. (Oxon.), Principal.
Royal Indian Engineering College, Coopers Hill—Prof. A. Lodge, M.A. (Oxon.), Professor of Mathematics
University of Allahabad—G. Thibaut, Ph.D., Principal of the Muir Central College, Allahabad.
University of Wales—J. Viriamu Jones, M.A., Vice-Chancellor.

In addition to the delegates officially appointed, the University entertained a number of distinguished guests, amongst whom the names of the following may be mentioned:—

Captain Abney, C.B., S. Kensington; Prof. W. G. Adams, King's College, London; Prof. H. E. Armstrong, City and Guilds Institute, S. Kensington; Prof. Arrhenius, Stockholm; Prof. Ayrton, City and Guilds Institute, S. Kensington; Prof. Barker, University of Pennsylvania, Philadelphia, U.S.A.; Mr. Shelford Bidwell; Dr. Bottomley, The University, Glasgow; Mr. C. V. Boys, London; Sir Frederick Bramwell, Bart.; Dr. Haig Brown; Prof. W. Burnside, Greenwich; Prof. Clifton, Oxford; Prof. Egoroff, St. Petersburg; Prof. Esson, Oxford; Sir John Evans, K.C.B.; Prof. Carey Foster, London; Dr. F. Galton; Sir A. Geikie; Prof. Andrew Gray, Bangor; Prof. Hele-Shaw; Mr. Hubert Herkomer, R.A.; Sir J. D. Hooker, C.B., G.C.S.I.; Prof. J. Joly, Dublin; Prof. Kayser, Bonn; the Hon. Sir W. R. Kennedy; Sir J. Norman Lockyer, K.C.B.; Major P. A. MacMahon; Prof. van der Mensbrugge, Ghent; Prof. Michelson, Chicago; Prof. G. M. Minchin, Coopers Hill; Prof. G. Mittag-Lefller, Stockholm; Mr. Ludwig Mond; Mr. J. Fletcher Moulton, M.P., Q.C.; Prof. Nernst, Göttingen; Prof. Karl Pearson, University College, London; Prof. Perry, Royal College of Science; Sir John Phear; Prof. Quincke, Heidelberg; Lord Rayleigh, Lord Lieutenant of Essex; Prof. H. F. Reid, Baltimore; Prof. Osborne Reynolds, Manchester; Sir W. C. Roberts-Austen, K.C.B., Royal College of Science, London; Sir Henry E. Roscoe, Vice-Chancellor of the University of London; The Rev. Dr. Salmon, Provost of Trinity College, Dublin; Prof. Schuster, Manchester; Sir R. Strachey, G.C.S.I.; Mr. J. W. Swan; Mr. H. Thornycroft, R.A.; Prof. H. H. Turner, Oxford; Prof. Voigt, Göttingen; Rt. Rev. Lord Bishop of Wakefield; Rear-Admiral Sir William Wharton, K.C.B.; Sir W. H. White, K.C.B.

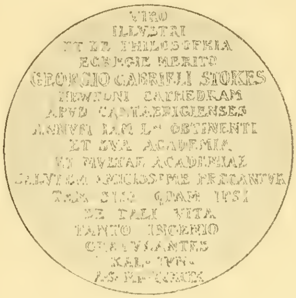
At 1.30 the Vice-Chancellor gave a lunch at Downing College to some 400 of the delegates and their hosts, and at 2.45 a congregation was held in the Senate House at which his Grace the Chancellor presided. The following address from the University was then read by Dr. Sandys, the Public Orator, and presented to Sir George Stokes, accompanied by a gold medal struck to commemorate the occasion.

Quod per annos quinquaginta inter nosmet ipsos Professoris munus tam praeclare ornavisti, et tibi, vir venerabilis, et nobis ipsis vehementer gratulamur. Iuvat vitam tam longam, tam serenam, tot studiorum fructibus maturis felicem, tot tantisque honoribus illustrem, tanta morum modestia et benignitate insignem, hodie paulisper contemplari. Anno eodem, quo Regina nostra Victoria insularum nostrarum solio et sceptro potita est, ipse eodem aetatis anno Newtoni nostri Universitatem iuvenis petisti, Newtoni cathedram postea per decem lustra ornaturus, Newtoni exemplum et in Senatu Britannico et in Societate Regia ante oculos habiturus, Newtoni vestigia in scientiarum terminis proferendeis pressurus et ingenii tanti imaginem etiam nostro in saeculo praesentem redditurus. Olim studiorum mathematicorum e certamine laurea prima reportata, postea (ne plura commemoremus) primum aquae et immotae et turbatae rationes, quae hydrostatica et hydrodynamica nominantur, subtilissime examinasti; deinde vel aquae vel aeris fluctibus corporum motus paulatim tardatos minutissime perpendisti; lucis denique leges obscuras ingenii tui lumine luculenter illustrasti. Idem etiam scientiae mathematicae in puro quodam caelo diu vixisti, atque hominum e controversiis procul remotus, sapientiae quasi in templo quodam sereno per vitam totam securus habitasti. In posterum autem famam diuturnam tibi propterea praesertim auguramur, quod, in inventis tuis pervulgandis perquam cautus et consideratus, nihil praeproperum, nihil immaturum, nihil temporis cursu postea obsolefactum, sed omnia matura et perfecta, omnia omnibus numeris absoluta, protulisti. Talia propter merita non modo in insulis nostris doctrinae sedes septem te doctorem honoris causa nominaverunt, sed etiam exterae gentes honoribus eximiis certatim cumulaverunt. Hodie eodem doctoris titulo studiorum tuorum socios nonnullos exteris e gentibus ad nos advectos, et ipsorum et tuum in honorem, velut exempli causa, libenter ornamus. In perpetuum denique observantiae nostrae et reverentiae testimonium, in honorem alumni diu a nobis dilecti et ab aliis nomismate honorifico non uno donati, ipsi nomisma novum cudendum curavimus. In honore nostro novo in te primum conferendo, inter vitae ante actae gratulationes, tibi omnia prospera etiam in posterum exoptamus.

The medal was designed by Mr. De Saulles, who designed the jubilee medals, and bears the head of the recipient in profile on the obverse, and some lines in Latin written by the Master of Trinity on the reverse. By the courtesy of the University Press, we are able to give the accompanying illustrations of the medal. The likeness is remarkably good, and the medal, replicas of which, in bronze, will be presented to the official delegates, was universally admired. We are informed that copies in bronze of the medal may be obtained from Messrs. Macmillan and Bowes. The number of medals struck is limited.

After the medal had been presented to Sir George by the Chancellor, Prof. Cornu advanced and presented on behalf of the Institute of France a copy of the Arago medal in gold. Immediately after the ceremony, honorary degrees of Doctor of Science were

conferred upon the following distinguished visitors :—Prof. M. A. Cornu, Member of the Institute of France, Professor of Experimental Physics in the École Polytechnique of Paris ; Prof. J. G. Darboux, Member of the Institute of France and Professor of Higher Geometry in the University of Paris ; Prof. A. A. Michelson, Professor of Experimental Physics in the University of Chicago ; Prof. M. G. Mittag-Leffler, Professor of Pure Mathematics at Stockholm ; Prof. G. H. Quincke, Professor of Experimental Physics in the University of Heidelberg ; and Prof. W. Voigt, Professor of Mathematical Physics in the University of Göttingen. Prof. F. W. G. Kohlrausch, Director of the Physikalisch-Technische Reichstanstalt, Charlottenburg, was unfortunately deterred by illness from attending to receive the degree which the University had been anxious to confer upon him.



The Stokes Jubliee Medal.

The following are the speeches delivered by the Public Orator in presenting to his Grace the Chancellor the several recipients of the honorary degree.

(1) PROF. CORNU (PARIS).

Primum vobis praesento artium plurimarum Scholae Parisiensis professorem, quem in hoc ipso loco die hesterno perspicuitate solita disserentem audivistis, virum non modo solis de lumine in partes suas solvendo, sed etiam orbis terrarum de mole metienda per annos plurimos praeclare meritum. Lucis in natura explicanda, quanta cum doctrinae elegantia, quanta cum experimentorum subtilitate, quam diu versatus est. Idem quam accurate velocitatem illam est dimensus, qua per aeris intervallum immensum lucis simulacra minutissima transvolitant,

"suppeditatur enim confestim lumine lumen,
et quasi protelo stimulatur fulgere fulgur."

Lucis transmittendae in λαμπαδηφορίᾳ quam feliciter lampada a suis sibi traditam ipse etiam trans aequor Atlanticum alii tradidit.

(2) PROF. DARBOUX (PARIS).

Sequitur deinceps vir insignis Nemausi natus, Parisiensium in Universitate illustri geometriam diu professus et scientiarum facultati toti praepositus. Peritis nota sunt quattuor illa volumina, in quibus superficierum rationem universam inclusit ; etiam pluribus notum est, quantum patriae legatus deliberationibus illis profuerit, quae a Societate nostra Regia primum institutae, id potissimum spectant, ut omnibus e gentibus quicquid a scientiarum cultoribus conquiritur, indicis unius in thesaurum, gentium omnium ad fructum, in posterum conferatur. Incepto tanto talium virorum auxilio ad exitum perducto, inter omnes gentes ei qui rerum naturae praesertim scientiam excolunt, sine dubio vinculis artioribus inter sese coniungentur.

(3) PROF. MICHELSON (CHICAGO).

Trans aequor Atlanticum ad nos advectus est vir insignis, qui ea quae professor noster Lucasianus de aetheris immensi regione, in qua lux propagatur, orbis terrarum motu perturbata, olim praesagiebat, ipse experimentis exquisitis adhibitis penitus exploravit. Lucis explorandae in provincia is certe scientiarum inter lumina numeratur, qui olim fratrum nostrorum transmarinorum in classe non ignotus, lampade trans oceanum e Gallia sibi tradita feliciter accepta, etiam exteris gentibus subito affulsit, velocitatem immensam eleganter dimensus, qua lucis fluctus videntur (ut Lucretii verbis utar)

"per totum caeli spatium diffundere sese,
perque volare mare ac terras, caelumque rigare."

(4) PROF. MITTAG-LEFFLER (STOCKHOLM).

Scandinavia ad nos misit scientiae mathematicae professorem illustrem, qui studiorum suorum velut e campo puro laudem plurimam victor reportavit. Idem Regis sui auspiciis, qui praemiis propositis magnum huic scientiae attulit adiumentum, etiam exterarum gentium ad communem fructum prope viginti per annos Acta illa Mathematica edidit, quae in his studiis quasi gentium omnium internuntium esse dixerim. Ipse Homerus (ut Pindari versus verbo uno tantum mutato proferam) ἄγγελον ἐσλὸν ἔφα τιμὰν μεγίσταν πράγματι παντὶ φέρειν· αὔξεται καὶ Μάθησις δι' ἀγγελίας ὀρθᾶς.

(5) PROF. QUINCKE (HEIDELBERG).

Universitatem Heidelbergensem abhinc annos quadraginta professorum par nobile spectroscopo invento in perpetuum illustravit. Adest inde discipulorum plurimorum in scientia physica praeceptor, qui et in instrumentis novis inveniendis sollertiam singularem et in eisdem adhibendis industriam indefessam praestitit. Ei qui in scientiae physicae ratione universa versati, viri huiusce inventis utuntur, etiam de sua scientia verum esse confitebuntur, quod de arte oratoria praesertim dixit Quintilianus :—"in omnibus fere minus valent praecepta quam experimenta."

(6) PROF. VOIGT (GÖTTINGEN).

Universitatem Goettingensem, a Rege nostro Hanoveriensi Georgio secundo conditam, vinculo non uno cum Universitate nostra coniunctam esse constat. Constat eandem etiam per annos prope quinquaginta Caroli Frederici Gaussii, scientiae mathematicae et physicae professoris celeberrimi, gloria esse illustratam, qui cum ingenio fecundissimo disserendi genus consummatum coniunxit. Iuvat inde professorem ad nos advectum excipere, qui scientiae eiusdem pulcherrimam nactus provinciam, etiam lucem ipsam et crystalla ingenii sui lumine illustravit.

After the congregation, a garden party was held in the beautiful old gardens of Pembroke College, where a numerous and brilliant company assembled and listened to the music of the Royal Artillery Band.

In the evening, a dinner, at which were present some 220 of the guests of the University and their hosts, took place in Trinity College Hall. His Grace the Duke of Devonshire presided, and after the health of the Queen had been drunk he proposed, in a felicitous speech, the health of the hero of the day. The toast was drunk with the greatest enthusiasm. The only other toasts were "The Guests," proposed by Prof. George Darwin, and responded to by Lord Lister ; and "The Chancellor," proposed by the Vice-Chancellor. In responding, the Chancellor thanked the Master and Fellows and Trinity

for their hospitality in granting the use of the Hall, and Dr. Butler replied on behalf of the College.

In addition to the guests who were more directly associated with the celebration of the jubilee, the following were present at the banquet:—Mr. Justice Mathew, the High Sheriff of Cambridgeshire, the Lord Lieutenant of Cambridgeshire, the Bishop of Ely, the Right Hon. A. J. Balfour, and many other distinguished guests.

This dinner brought the official proceedings to an end, but on Monday a meeting of the Philosophical Society was held for the presentation of papers to be published in a special volume of the Society's *Transactions* commemorative of the long connection of Sir G. G. Stokes with the Society. The following are amongst those who formally communicated papers:—

I. By Prof. M. G. Mittag-Leffler: On the analytical representation of a uniform branch of a monogenic function.
II. By Prof. H. Poincaré: The theory of groups.
III. By Dr. L. Boltzmann:
IV. By Prof. A. Righi:
V. By Prof. A. A. Michelson: On the echelon spectroscope.
VI. By Major P. A. Macmahon, R.A.: Application of the partition analysis to the study of the properties of any system of consecutive integers.
VII. By Lord Kelvin: On diffraction of solitary waves.
VIII. By Prof. A. Schuster: On the periodogram of magnetic declination derived from twenty-five years' observations at the Greenwich Observatory.
IX. By Prof. W. D. Niven: A general method of determining free electric distributions by successive approximations.
X. By Prof. G. D. Liveing: The influence of temperature on the absorption spectra of salts.
XI. By Prof. A. R. Forsyth: On the integrals of systems of differential equations.
XII. By Mr. J. Larmor: On the general theory of the optical relations of magnetism.

Together with papers by Prof. J. J. Thomson, Dr. E. W. Hobson, Mr. E. H. Griffiths, Mr. W. N. Shaw, Mr. E. W. Brown, and Mr. H. M. Macdonald.

In conclusion, it may be stated that from beginning to end the celebration was a complete success. The weather played an important part in securing this success, but the thanks of all who assisted at the jubilee must also be tendered to those at Cambridge who took such careful forethought for their convenience and comfort.

*The Cambridge Review* for June 1 publishes several contributions referring to the jubilee, and issues as a special supplement an excellent portrait of Sir George Stokes. Prof. J. J. Thomson gives an appreciative account of the scientific career and work of the esteemed Lucasian Professor. In concluding the article, he remarks:—

"By his researches on hydrodynamics he has founded a new branch of the science; in optics he has, to use the words of Lord Kelvin, been the teacher and guide of his contemporaries; he was the first to enunciate in his lectures the principles on which spectrum analysis is founded; he unravelled the laws of fluorescence; he investigated the variation of gravity over the surface of the earth; he has solved problems of the greatest difficulty in pure mathematics; while the latest of his long series of researches is his remarkable paper on the nature of the Röntgen rays. His papers are the classics of science; they are remarkable, not only for the results obtained, but also for their perfect clearness of expression and thought, for the elegance of the mathematical methods, for their maturity of judgment and for that care and finish on which so much of the impressiveness of a paper depends.

The little more and how much it is,
The little less and what worlds away.

These researches show the combination of supreme mathematical and experimental power; with simple apparatus and without the appliances which are now at the command of physicists, he has made experiments which have settled some of the most crucial points in optics, and which will be quoted as long as science exists. The rooms in Pembroke, where he made many of his experiments, will in the history of science and of the University be associated with those in the Old Court of Trinity, where Newton made the prism reveal the nature of white light. And, indeed, there are many points of resemblance between the careers of Newton and of Stokes: both held the Lucasian Professorship, both were Presidents of the Royal Society, both represented the University in Parliament; and the resemblance is not confined to the offices they held, it extends to their type of mind. Often, in reading Stokes's papers, we feel this is just how Newton would have treated this point, these are the deductions which Newton would have drawn."

Prof. Jebb contributes the following ode to the *Cambridge Review*.

To Sir George Gabriel Stokes.

June 1, 1899.

Clear mind, strong heart, true servant of the light,
True to that light within the soul, whose ray,
Pure and serene, hath brightened on thy way,
Honour and praise now crown thee on the height
Of tranquil years. Forgetfulness and night
Shall spare thy fame, when, in some larger day
Of knowledge yet undream'd, time makes a prey
Of many a deed and name that once were bright.

Thou, without haste or pause, from youth to age,
Hast moved with sure steps to thy goal. And thine
That sure renown which sage confirms to sage,
Borne from afar. Yet wisdom shows a sign
Greater, through all thy life, than glory's wage;
Thy strength has rested on the Love Divine.

## CENTENARY OF THE ROYAL INSTITUTION.

The celebration of the centenary of the foundation of the Royal Institution was commenced on Monday by a banquet given by the managers of the Institution in the Hall of the Merchant Taylors' Company. The Duke of Northumberland, president of the Institution, occupied the chair. The Prince of Wales was present, and a number of distinguished men of science were among the guests. Reference to a few points connected with the history and work of the Institution were made in the course of the evening. In acknowledging the toast of his health, the Prince of Wales said:

I consider it a great privilege and honour to take part, as vice-patron of this Institution, in the celebration of its 100th anniversary. I had an early acquaintance with the Royal Institution. Although it is nearly half a century ago, I have not forgotten that just after Christmas my brother, the Duke of Coburg, and myself were sent to attend the lectures given by the great Prof. Michael Faraday. I have not forgotten the clear way in which Prof. Faraday explained difficult scientific problems, and showed the chemical experiments which were then the order of the day. Among the most remarkable discoveries with which the Institution is associated is that of Davy, which has saved thousands of lives. It is needless to speak of the researches of Faraday, whom I knew; and in our own time of the remarkable achievements in several branches of science of Lord Rayleigh. I thank you once more most cordially, and express my high appreciation of this great and important centenary event. I am glad also to see so many distinguished foreigners who have come over to take part in this interesting gathering.

The Duke of Cambridge proposed "The Royal Institution of Great Britain," and in doing so remarked that the declared object of the Institution was the diffusion of knowledge and the

introduction of useful mechanical inventions, and the means were to be courses of philosophical lectures and experiments illustrating the applications of science to daily life.

The Chairman, in acknowledgment of the toast, said that it was a great honour that so many eminent representatives of foreign science had honoured with their presence the centenary of the Institution. It was just 100 years ago when the Institution entered upon its present premises. A long roll of names had lent lustre to their labours. Davy, Faraday, Young, Tyndall—above all, they should remember their founder, Benjamin Thomson, Count Rumford, whom it was easy to criticise, but whose virtues had been productive of great results. The work of the Institution had been in large measure the carrying out of Count Rumford's ideas. It was said that he intended an institution of a more practical or industrial character than the Institution now was. But changes had taken place. Facilities for communicating new discoveries were 100 years ago few; competition was less keen; there was then much dislike of innovation, and there was extreme jealousy with the working classes of any reduction of manual labour. It was thus necessary to popularise discoveries; and that was the aim of their founder. But now every such discovery was soon heralded to the public. Popular magazines had now articles on the manufacture of liquid air and other subjects of an abstruse character. Towards this wide diffusion of science the Royal Institution had largely contributed. Their principal objects were research, for which their laboratories gave ample means, and in respect of which special gratitude was due to Dr. Mond for his noble gift, and to Mr. Spottiswoode for his collection. The second object was to bring the results of research to the knowledge of those who could appreciate them, and these results were expounded in the evening lectures of the Institution. Thirdly, this knowledge was popularised by the afternoon lectures; and, finally, the rising generation were stimulated by the juvenile lectures to those who, it was hoped, were destined to take their part in future scientific investigation.

On Tuesday afternoon a commemoration lecture was delivered at the Institution by Lord Rayleigh, the Prince of Wales being present.

In the course of his remarks, Lord Rayleigh is reported by the *Times* to have said that though his was intended to be a commemorative lecture, the idea of commemorating all the work that had been done at the Royal Institution was hopeless. Remembering that on other occasions he had spoken of the achievements of Faraday and Tyndall, he thought on this occasion he would do well to go still further back in the century and speak of Dr. Thomas Young, one of the earliest professors of the Institution. Young occupied a very high place in the estimation of men of science—higher, indeed, now than at the time when he did his work. His "Lectures on Natural Philosophy," containing the substance of courses delivered in the Institution, was a very remarkable book, which was not known as widely as it ought to be. Its expositions in some branches were unexcelled even now, and it contained some things which, so far as he knew, were not to be found elsewhere. The earlier lectures dealt with mechanics, and the reader would find as sound an exposition of that science as could be imagined. Elastic resilience, or what we should now call potential energy, was better dealt with there than in any other treatise he knew, for Young discussed the subject with remarkable ingenuity, showing that the phenomena exhibited by two bodies coming into collision were comprehended under two cases. In the province of sound, Young was the originator of many of the most important principles on which the doctrine was now expounded, but it was with optics that his name was most closely associated, for Fresnel and he were the builders of the great structure of the undulatory theory. Lord Rayleigh then mentioned some of the points in which Young's good work had been overlooked. In Young's time one question of discussion was the change of the focus of the eye for varying distances. One suggested explanation, that accommodation was affected by an alteration in the external convexity of the eye, Young proved to be wrong by drowning his eye in water. This virtually altered the convexity, yet the power of accommodation remained, and he therefore concluded it was due to a muscular alteration in the internal lens of the eye. Young was singularly successful in the theory of cohesion and capillarity, in which some of his earliest work was done, and he was the first to deduce an estimate of molecular dimensions from data afforded by that theory. The size of the molecule, according to his calculations, was not very different from that admitted at the present day. In the theory of the tides he made great advances, while his views on heat were very interesting, since he had the utmost contempt for the idea prevalent in his time that it was a separate entity, and expressed the hope that in time philosophers might arrive at a true conception of its nature as motion. Speaking of work which had been done at the Institution by men who held no regular appointment in it, the lecturer noted that Wedgwood, in conjunction with Davy, was the first to produce anything that could be called a photograph, while instantaneous photography, such as was required for rapidly moving objects, was carried out for the first time by Fox Talbot in the laboratory of the Institution.

Another commemoration lecture is to be delivered as we go to press. Upon the invitation of the teachers of natural science in Oxford University, honorary members of the Institution will visit the University to-day.

The principal historical apparatus in the Institution has been on view during the centenary celebration. An interesting souvenir of the centenary is an illustrated brochure referring to William Spottiswoode, and to his collection of physical apparatus just presented to the Institution by his son, Mr. W. H. Spottiswoode. The souvenir includes a memoir of Spottiswoode, reprinted from NATURE of April 26, 1883; a list of lectures delivered by him at the Royal Institution, notes on some of the more important objects in the collection of apparatus, a reprint of a paper by Spottiswoode on the laboratories of the Institution, and a chronological list of original work developed at the Institution. A photogravure of Spottiswoode, and a number of brilliant half-tone pictures of sets of objects in the collection of apparatus, form part of Mr. Spottiswoode's interesting pamphlet.

## *THE HEIGHT OF THE AURORA.*[1]

A GOOD story used to be told some years ago of a candidate, who, when undergoing the torture of a *vivâ voce* examination, was unable to reply satisfactorily to any of the questions asked. "Come, sir," said the examiner, with the air of a man asking the simplest question, "explain to me the cause of the aurora borealis." "Sir," said the unhappy aspirant for physical honours, "I could have explained it perfectly yesterday, but nervousness has, I think, made me lose my memory." "This is very unfortunate," said the examiner, "you are the only man who could have explained this mystery, and you have forgotten it." One is not prepared to say that exact and complete knowledge of the cause of this curious phenomenon has greatly advanced since the time when the examiner made this crushing rejoinder, and it is therefore fortunate to have to treat of only one of the difficulties with which the whole problem is beset—the height at which the light manifests itself, or the limits of altitude above the earth's surface at which it may be seen. But a preliminary difficulty arises in connection with even this bare statement. Is the aurora borealis a localised phenomenon? Has it a habitation as well as a name? Or is it, like the rainbow, an optical exhibition resulting from the operation of certain physical causes. In the case of the rainbow, the causes admit of a tolerably simple explanation, and little is to be learnt from the study of its general features as seen in the sky; certainly we should not think it betokened any great show of wisdom to attempt to determine its height by any method of measurement or triangulation. The angular altitude is settled for us in a quite different manner, and it may

[1] "The Altitude of the Aurora above the Earth's Surface." By Prof. Cleveland Abbe. ("Terrestrial Magnetism," vol. iii., 1898.

be that we are displaying a crass ignorance in endeavouring to apply to auroræ methods of measurement which depend for their success upon an apparent displacement, due to a real change in the position of the observer. Students of trigonometry are taught at a very early stage the method of determining the distance of an inaccessible object, visible from two positions, and the elementary process employed, depending on the solution of a triangle, remains the favourite method of determining the height of the aurora. But just as our student knows that a successful solution of the problem demands that the angles must refer to a concrete object, so the observer of an aurora asks that this fitful light should have a definite "locus," that can be simultaneously seen and identified by two or more observers. Practically, this fundamental condition is not always easily satisfied, and other methods have in consequence been suggested which are founded on a supposed knowledge of the origin and behaviour of the auroral light. We may say at once that these methods, often ingenious in themselves, are so unsatisfactory in application that they can be passed over with a very brief mention.

There is no doubt but that the light out of which the auroral phenomena are formed emanates from a certain circumscribed region, but the real question is whether the arches and beams, the streamers and waves, the curtains and folds, with all the varied nomenclature that has been used to describe special features, are definite concrete objects. The fact that the aurora is accompanied with a special and presumably constant spectrum, possessing easily recognisable characteristics, does not help us at all to settle the question. That we have a source of light is admitted. The point at issue is, to what extent is it a subjective phenomenon, and how far does each observer see his own aurora as an optical illusion. Manifestly, those who accept the subjective theory have to encounter many objections. No one likes to admit that he is deceived in the character of a phenomenon so apparently real as that presented by a fine auroral display, though he will readily acknowledge that perspective must introduce some misleading features. Prof. Cleveland Abbe has, however, summed up the evidence with great care and completeness, and come to the conclusion that the idea of an individual existence must be definitely relinquished. He has been led to this conclusion from an examination of the various attempts that have been made to determine the height of the aurora; and whether we accept this decision or not, we shall at least be prepared to follow him in the assertion that the determination of the altitude of the aurora is a much more delicate problem, and perhaps also a more indefinite problem, than we have hitherto believed.

The evidence tending to this latter conclusion can be divided under many heads. We shall content ourselves with exhibiting two—one depending upon actual observation and measurement, the other resting upon theory and suggestion. The observers who have made the height of the aurora a special study can be grouped into two families—one represented by Richardson, Franklin, Hooker, and Silberman, who have actually seen the aurora below the clouds, or between themselves and neighbouring objects; and others like Loomis, Boscovich, and Twining, who place the height anywhere between 400 and 1000 miles. Between these advocates for a "ground" theory, and those who perceive a high aerial origin, we have a whole host of observers who are mainly led to their results by the selection and rejection of certain of their observations, if they are numerous, or have drawn their conclusions from single and accidental results. For the statement of claim of those who argue that the aurora is entirely confined to the lowest stratum of the earth's atmosphere, we must trust entirely to description. Measurement can evidently play no part, any more than it can on a bank of fog or a shower of hail. An admirable description, and one that would carry conviction to every impartial reader, if we could give it fully, has been written by Prof. J. P. Lesley, the distinguished geologist, of what he saw at Little Glace Bay, about seventeen miles from Sydney, Cape Breton: "It was my good fortune to observe an aurora, which to my eyes was embodied in and swept the earth with successive banks of Cape Breton fog. . . . In this fog bank hung, as it were, a brilliant curtain of light, with a wide fringe or flounce of maximum brilliancy, along the bottom edge, the light fading upwards along the curtain, but traceable to the very zenith, and the curtain stretching from the eastern horizon out at sea to the western horizon on the low hill-tops. The perspective was perfect. The curtain was evidently vertical, thin, straight, long enough to reach from one limit of the vision to the other, and floating broadside before the south wind towards the north. No reasoning could convince us (he had a companion) that these were not elements of the phenomenon, and, moreover, that the lower edge of the bright fringe was more than one or two hundred yards away at its nearest point when we first saw it. Its rate of departure from us was evidently that of the fog bank, or that of the gentle south wind then blowing. The perspective of the whole curtain changed in conformity with that supposition. We had both spent our lives in topographical work, and no record of triangulation made upon this aurora would alter my conviction of the posture and movements of the beautiful object, derived from the natural triangulations of the unassisted eye." Prof. Lesley further relates that he witnessed successive repetitions of the same beautiful appearance, but feebler in intensity, as though produced by the same causes gradually growing less and less active, from a process of exhaustion. Of the accuracy of his testimony he can entertain no doubt, and urges that it is unreasonable that the positive observations of those who have witnessed these displays should be despotically overriden by the trigonometrical calculations of other students. We are inclined to agree with him. It might, of course, be urged by those who consider that the upper and attenuated regions of the atmosphere are necessary for the production of auroral light, that such an exhibition was not a true aurora, and that if examined spectroscopically the light would not show the characteristic lines, nor would the magnetic instruments in the neighbourhood be agitated in the manner with which we have been made familiar when auroræ are present. On these points there seems to be no evidence, nor, so far as is known, have other physicists, who, like General Sabine, have "walked through an aurora as one would pass through a mist," verified their convictions.

But if the deductions of those who trust to the evidence of their senses can be set aside as affected by self-deception, others who rely on elaborate measurements are hardly in better case. With more pretentious methods, more rigorous criticism can be applied. Into the details of this criticism it is not convenient to enter here, involving as it does that much-debated quantity the "probable error," and still more recondite criteria for the rejection of discordant observations. But we have a right to expect an intelligible result, and this is not in every case forthcoming. If a man carefully surveyed a field with the view of determining its superficial area, brought out as his result a minus quantity, we should necessarily have a difficulty in explaining his deductions. And, without any exaggeration, it is precisely results of this character which are too frequently obtained from attempted measurements of auroræ. Of course, in the case of an object so ill-defined as an auroral arch, one expects to find large observational errors. But these

errors should have less effect in proportion as the conditions for securing accuracy in the solution of the problem increase. For instance, if we are going to measure a distance of two, four, or six hundred miles, a base of a mile or less in length will give us a very ill-conditioned triangle; but as we increase the length of the base, we should expect greater consistency in the results. Unfortunately this expectation is not realised. As an illustration, we select, out of the mass of measures that Prof. Cleveland Abbe has collected, three series of observations. The earliest of these sets was made in 1839, by MM. Bravais and Lottin in Norway, in latitude about $+70°$. The stations selected provided a base line about ten miles in length. Even at this moderate distance, the two expert observers could not recognise the same features in the auroral arch, or be certain that the angles measured with their theodolites referred to the same point. But Bravais, greatly daring, boldly applied trigonometrical methods, and deduced a parallax with mathematical rigour. Out of seven measures, as shown below, three parallaxes are negative and four positive, the total range being more than eleven degrees.

| | h. m. | Parallax ° ′ | | h. m. | Parallax ° ′ |
|---|---|---|---|---|---|
| 1839 January 12, | 5 37 | −3 42 | 1839 January 21, | 6 2 | −1 34 |
| ,, ,, 12, | 6 2 | +2 13 | ,, ,, 21, | 7 3 | +1 4 |
| ,, ,, 12, | 9 30 | +9 52 | ,, ,, 21, | 7 33 | +0 45 |
| ,, ,, 12, | 10 36 | −0 8 | | | |

Bravais concluded from all his observations that the mean altitude of the auroral arch is between 100 and 150 kilometres, but suggested that in order to determine "the parallax of the aurora more precisely than we have been able to do, it would be necessary to employ a longer base than ours, say about 100 kilometres in length, and directed as nearly as possible parallel to the vertical plane through the culmination of the arch." Fifty years later, Bravais' suggestion was carried out. Tromholt of Rostock, in Norway, occupied one of the stations near the scene of Bravais' earlier investigations, but extended the base line to a length of 66 miles. From one end of this base line, Tromholt made no less than 634 measurements, while 367 were made from the companion site. On comparing the results, however, only sixty corresponded as to time and referred, or were supposed to refer, to identical objects. These sixty were again reduced to forty-two, for reasons which do not appear; but it would be scarcely uncharitable to suggest that the remainder gave negative or impossible parallaxes. This modest remainder reminds one of Falstaff's "half-pennyworth of bread to his intolerable deal of sack." The final result, however, taken for what it is worth, assigns altitudes to the auroræ varying from 19 to 217 kilometres. Variations so great in amount cannot inspire confidence.

It might, however, be objected that in the Tromholt series, since the observers were separated some 100 km., that only the upper features of the aurora could be visible simultaneously from both stations, and that if the true or localised aurora was confined to the lower strata of the atmosphere, more or less illusory results might be expected. But we have a third series, made in about the same latitude, in which the observers were stationed only about a third of a mile apart, where they were in constant telephonic communication with each other, and where, therefore, the conditions were favourable to the removal of some of the difficulties that beset the parallactic method. Without quoting in detail the results obtained, it will be sufficient to say that, on discussion, the number of positive and negative parallaxes, even after judicious rejections, was found to be seventeen and twenty-three respectively, and that consequently no trustworthy value of the height could be deduced. Prof. Cleveland Abbe shows in this particular case how the calculus of probabilities has been forced in order to derive a plausible altitude from these observations. There is, however, no necessity to labour the point. We are simply concerned to show that the method tried under various conditions fails to give consistent results. Those who believe that the aurora is confined to the upper regions of the atmosphere reject the largest parallaxes, while those who are fighting for a low aurora will only accept the large values. The one fact which seems to stand out clearly after much patient examination is that the parallax does not increase with the increase of the length of the base line, or, in other words, it cannot be a true parallax. There is no dearth of reasons to explain these discrepant results. The inevitable error of observation arising from the feebleness of the light, the want of clear definition at the boundary of the arch, the possible movement of the object itself, and the want of absolute synchronism in the measurements at the stations, would be more than sufficient to make the method untrustworthy.

In presence of these difficulties, other methods depending on quite different principles have, as before intimated, been suggested and applied. The general principle involved is to derive the height from observations made at a single station, thus eliminating the second observer and the errors he introduces, putting in his place some more or less plausible suggestion as to the origin of the aurora itself. Galle, for instance, assumed that an auroral streamer is parallel to a free magnetical needle on the earth's surface, vertically below the beam. By observing the zenith distance of the auroral corona in his magnetic meridian, he obtained the angle made by his vertical with the parallel lines of light that compose the aurora, or the dip of the needle suspended in the region whence the light emanates. The magnetic charts show at what point on the earth's surface the needle would have the same dip. This gives a right-angled triangle whose base is known, and whose vertical side is the desired height. The weak point in the method is the assumption that the dip of the needle in the place where the corona is presumed to be coincides with that at the earth's surface immediately beneath it. Another method that has been applied is due to Bravais. It assumes that the auroral arch throughout its whole extent exists at a uniform distance above the earth's surface. If this assumption were justified, the determination of the azimuth and altitude of the two ends, and of the summit of the arch, would lead to a knowledge of its height. The method has been repeatedly tried with some modifications concerning the curvature of the arch, and of the position of the centre of the circle; but the very number of the variations that have been made condemns the accuracy and the applicability of the method. The observed apparent velocity of the motion of the arch, as seen from two stations in a magnetic meridian, has also been tried; and indeed, without further enumeration of the plans that have been suggested, one may say that the ingenuity and industry brought to bear upon this problem have been such, that if the definite beams and arches possessed a real existence and a definite locus, its solution would have been assured. That the parallax has remained so long indeterminate is probably due to the fact that the question has not been broached along appropriate lines. In his careful review, Prof. Cleveland Abbe makes some practical suggestions which, if applied, would go a great way to show how far optical illusion and perspective displacement affect this luminous phenomenon, which for so long has supplied poets with a simile for instability, and which under scientific examination gives additional point to the well-known lines of Burns:—

"Like the Borealis race
That flit ere you can point the place."

## THE TOTAL ECLIPSE OF THE SUN, MAY 1900.

WE have received the following circular from the U.S. Naval Observatory, Georgetown Heights, Washington, D.C., dated May 17.

In anticipation of the total eclipse of the sun May 28, 1900, the United States Navy Department has arranged with the Secretary of the Treasury to have admitted free of duty the instruments of foreign astronomers who may come to this country to observe the eclipse.

To this end astronomers abroad who contemplate an expedition to the United States are invited to notify the Superintendent of the Naval Observatory of the probable date of their arrival, with the name of the port at which they propose to disembark. The Navy Department will forward to the consuls of the different countries to which these observers belong, stationed at the ports in the United States at which the gentlemen shall arrive, a letter stating their purpose in travelling, which letter will be countersigned by the consul and presented to the collector at the port as a proof of their identity. Upon this the collector will extend all proper facilities for the speedy delivery of the instruments in question, free of duty and charges.

The Superintendent of the Observatory will be glad to hear from each of the proposed expeditions, in order that he may render such assistance as lies in his power. The path of totality extends through a thickly settled portion of the country, including some principal cities. Facilities for transportation are excellent, but it is recommended that instruments be securely packed and marked "delicate instruments—handle with care." The climate at that season is warm. The chances for clear weather are good.

Full information regarding routes of travel to proposed points, and other particulars, can best be obtained through consuls. Through the regular diplomatic channels notice should be conveyed to the local authorities of the city or town selected as a post of observation.

This Observatory will issue a pamphlet of instructions, containing large scale maps showing path of totality.

C. H. DAVIS,
Captain, U.S.N., Superintendent.

## NOTES.

THREE Fellows of the Royal Society have had honours conferred upon them on the occasion of her Majesty's eightieth birthday. Prof. J. S. Burdon Sanderson, Regius professor of medicine in the University of Oxford, has had the dignity of a baronetcy conferred upon him; and physiology is also honoured in the person of Prof. Michael Foster, joint-secretary of the Royal Society, and president-elect of the British Association, who has been appointed to be K.C.B. The promotions from C.B. to K.C.B. include Mr. W. H. Preece, who recently retired from his position as engineer-in-chief of the General Post Office.

AT the annual meeting of the Royal Society for the election of Fellows, the fifteen candidates nominated by the Council were elected into the Society. The names and qualifications of these candidates were given in NATURE of May 11 (p. 31).

THE five vacancies in the list of Foreign Members of the Royal Society have been filled by the election of the following: Prof. Ludwig Boltzmann, of the University of Vienna; Prof. Anton Dohrn, late Director of the Zoological Station, Naples; Prof. Emil Fischer, of the University of Berlin; Dr. Neumayer, of Hamburg; and Dr. Treub, Director of the Botanical Gardens, Buitenzorg.

THE Académie Royale des sciences de Turin announces that the Vallauri prize of 30,000 lire (£1200) will be awarded for the most important and celebrated work in the realm of physical science—using this term in a wide sense—published between January 1 of this year and December 31, 1902. The prize will be awarded without consideration of nationality, and no members of the Academy can participate in the competition. No account will be taken of works in manuscript. The president of the Academy is Prof. Guiseppe Carle, the secretary of the section of physical sciences is Prof. A. Naccari.

THE anniversary meeting of the Royal Geographical Society was held on Monday, and the medals awarded by the Council of the Society, as announced in our issue of May 11, were presented. The meeting was also made the occasion for the American Ambassador to present Sir John Murray with the gold medal awarded to him by the Geographical Society of New York. The medal contains the following inscription:—"Cullum Geographical Medal. Awarded to Sir John Murray, K.C.B., naturalist, deep sea explorer, oceanographer, editor of *Challenger* Reports, 1899."

IT is reported that the *Bakan* transport has left the Neva on her voyage to Spitsbergen. She has a crew of ninety men and eight officers, including Captain Ergomysheff, who is in command.

EFFORTS are being made in New York to form an American Physical Society similar to the Physical Society of London and the Deutsche physikalische Gesellschaft.

IT is announced in *Science* that Prof. F. L. O. Wadsworth has been appointed by the managers of the Western Pennsylvania University to succeed Prof. J. E. Keeler as director of the Allegheny Observatory. Dr. J. L. Wortman, of the American Museum of Natural History, has resigned his position in the museum in order to take charge of the new collections of vertebrate fossils in the Carnegie Museum at Pittsburg.

THE Rome correspondent of the *British Medical Journal* states that since the beginning of May, Prof. Koch and his assistants have installed themselves at the Municipal Hospital of Grosseto, where they are continuing their researches on malaria. Grosseto is a town situated in the line between Genoa and Rome, and is surrounded by an extensive plain, which in olden times was the Lacus Prelius of Cicero. This lake gradually became a morass and caused malaria. By skilful drainage and other means, the Italian Government has converted nearly the whole of this morass into valuable pasturage, and has thus lessened greatly the malaria. It is said that Prof. Koch intends to go to South Africa to continue his studies there when he leaves Grosseto.

A REUTER telegram from Stockholm, dated June 6, says that the Anthropological and Geographical Society in Stockholm has received the following telegram from Herr Vathne, a shipowner at Mandal:—"Captain Hueland, of the steamship *Vaagen*, who arrived there on Monday morning, reports tha when off Kola Fjord, Iceland, in 65° 34′ north lat., 21° 28′ west long., on May 14 he found a drifting buoy marked 'No. 7.' Inside the buoy was a capsule, marked 'Andrée's Polar Expedition,' containing a slip of paper, on which was written the following:—'Drifting buoy, No. 7. This buoy was thrown out from Andrée's balloon on July 11, 1897 10.55 p.m., Greenwich mean time, 82° north lat., 25° east long. We are at an altitude of 600 metres; all well. Andrée, Strindberg, Fraenckel.'" Herr Andrée made his ascent from Danes Island on July 11, 1897, at 3 o'clock in the afternoon, so that when the buoy was thrown out the explorer had only travelled seven hours and fifty-five minutes.

A CONFERENCE of representatives of Sea Fishery Boards with officials of the Board of Trade took place at Westminster on Tuesday, under the presidency of Mr. Ritchie. In his remarks

upon opening the proceedings, Mr. Ritchie referred to the forthcoming fishery conference at Stockholm, and said that whilst the Government were anxious to have the purely scientific branch of the subject dealt with, they had also instructed their delegates to see whether some agreement could not be come to whereby there should be an increase of the productiveness of the fisheries, and thus secure a permanent increase of fish in the markets adjoining the North Sea. Sir John Murray, Mr. Arter, and Prof. D'Arcy Thompson will represent the Government at the conference.

THE following State legislation in 1898, mentioned in the *American Naturalist*, is of interest to naturalists. New Jersey has provided for a State entomologist; Louisiana has passed a Bill providing for the establishment of a biological station in the Gulf of Mexico, to co-operate with the United States Fish Commission for the investigation of problems affecting the fisheries of the State; New York has forbidden the killing at any time of wild moose, elk, caribou, and antelope; Ohio has repealed the law relative to the trapping or killing of musk-rats, mink, and otter.

Model of the Moon. Field Columbian Museum. (Diameter, 19 feet.)

SIR CHARLES TODD has communicated some interesting notes to the Adelaide *Advertiser* of April 18, relating to the meteorology of South Australia during the past summer (November to March). November was one of the coolest on record, being 2°·8 below the average; this was followed by a hot December, with a mean temperature of 76°·4, which has only once been exceeded. January was the coldest during the forty-two years' records at Adelaide, and was followed by a hot February. The highest temperature during the month was 113°·6, which was the hottest day since January 1880. During the summer the thermometer read over 90° on forty-two days, of which about half were over 100°. The mean temperature for the five months, 71°·6, is just above the average.

AN apparatus, by means of which a record is automatically taken of the extent to which the steering wheel of a ship is moved and the helm put over, has been devised by Mr. J. E. Liardet. The apparatus consists principally of a couple of drums on which a "tape" or long strip of paper is wound. The movement of the wheel actuates these drums, unwinding the tape from one and winding it on the other, the motions being obtained by suitable toothed gearing. In the same way, a pencil fixed to a holder is caused to move to one side of the central line of the paper if the helm is put to port, and the other side when the helm is starboarded, the amplitude of the movement of the pencil being proportionate to the angle of helm. In this way, an accurate record may be kept of the number of times and the amount the helm is shifted. It is proposed to add clockwork mechanism, so that the paper will be continuously unwound at a uniform speed, and the time at which any movement is made will thus be recorded.

ONE of the most interesting additions to the Field Columbian Museum in 1898 was the Schmidt-Dickert relief model of the moon, an illustration of which we are enabled to give by the courtesy of Mr. F. J. V. Skiff, the director of the museum. The model is in the form of a hemisphere having a diameter of 19 feet, and it exhibits very accurately the surface features of the moon. It was prepared with great care from the charts of Beer and Madler, and of Dr. Schmidt, of the Athens Observatory. Five years were occupied in its construction. The sections of the model have been for several years in Chicago, but they have only been available to the public at rare intervals. It is through the generosity of Mr. L. W. Reese that this noteworthy object has been added to the collections in the Field Columbian Museum. The model as exhibited will undoubtedly prove of great interest to the public generally, and especially to students of astronomy. Chicago is fortunate in possessing such a striking representation of lunar topography.

THE absence of palæolithic implements from Scotland has been explained by glacial conditions or the submergence of the country. Neither of these explanations seems to the Rev. F. Smith to be adequate, for during part at least of the period in question (as during the deposition of the *Cyrena fluminalis* beds) the climate of Britain was warmer than it is now, and the geographical occurrence of palæolithic remains in England and France evidence the period to have been that of great upheaval, and it is improbable that Scotland was then submerged. He finds (*Proc. Philosoph. Soc.*, Glasgow, 1899) a more sufficient explanation in the suggestion that the searchers were looking for the wrong thing. The ordinary types being flints, flint specimens were sought in Scotland; but no flint exists *in situ* in Scotland. Either palæolithic man was limited in his habitat to the geographical occurrence of flint, or that such specimens as might exist in Scotland would be fashioned of the rocks native to the country, and would be lacking in the peculiar characteristics of flaked flint. The first assumption is probably erroneous, so Mr. Smith has spent many years to an investigation of the alternative proposition. Under analogous conditions to those which obtain in the Somme Valley, he has found in the valleys of the Forth, Tay, Earn, Allan, Dee and Don, and in the Clyde Estuary, stones of quartzite, basalt, and various igneous rocks which certainly bear a superficial resemblance to well-known palæolithic types. The author acknowledges that these stones can only be fully appreciated by being handled, and that his illustrations do not do them justice. The author's contention is certainly tenable, but the evidence of the specimens can only be gauged by actual inspection.

THE origin of religion has long been a difficult problem, and is likely to remain obscure for some time yet. The germ, according to Tylor, lies in the belief in spiritual beings; Lippert finds it in the worship of the soul. Herbert Spencer has stated that ancestor worship is the root of every religion, and again that there is strong warrant for the inference that ghost-propitiation is the origin of all religions. C. L. Henning attempts in *The American Anthropologist* (vol. xi. p. 373) to solve the question from quite another standpoint. All the investigators in this field, without exception, have neglected one principal factor in their respective researches—the economic conditions. Primitive man had no religion; this was the product of much later times, and did not arise from a so-called "religious sentiment." A system of social virtues, or in other words a primitive social morality, was early developed owing to men being united in hordes; but this has nothing to do with religious perceptions. A man who during his life ameliorated the economic conditions of his tribal companions was not forgotten after his death; of this there are innumerable past and present examples. Such men after their death became heroes or benefactors of their respective tribes. The veneration they enjoyed during life changed after their death into ancestor worship, and later on into soul worship; the two latter forms of worship are the beginning of the historical evolution of religion.

THE Geology and Agriculture of the Department of the Lozère, in the south of France, forms the subject of an elaborate article by M. Ernest Cord (*Bull. de la Soc. d'Encouragement pour l'Industrie Nationale*, Paris). In the second part of his work, published in April, the author gives an account of the Triassic and Liassic strata. The Trias, which consists mostly of sandstones and conglomerates, with some argillaceous layers, occupies small tracts of woodland with fine chesnut-trees and much oak coppice. The central plateau of the Lozère, consisting of gneiss, mica schist, and granite, is bordered by Jurassic rocks which formerly overspread this group of ancient rocks. From the Rhætic Beds to the Upper Lias the various stages are well represented. Much of the soil on the Rhætic formation is a kind of arkose, derived from granitic débris in the strata, and it is dry and sandy; nevertheless there are calcareous ingredients, and the beech flourishes. The higher portions of the "Infra-Lias" and the Lias proper consist mainly of limestones, marls and clays, and they form a rich agricultural district—cereals, vegetables and fruit being cultivated. Attention is directed to the magnesian limestones, which form striking features in the upper part of the "Infra-Lias." These limestones are much fissured, and the streams in many instances pass underground and reappear at lower levels. Several illustrations of these swallet-holes are given. The magnesian waters have an injurious effect on those who are accustomed to drink them, and it is noted that goitre is met with among the residents in these districts.

IN the *Verhandlungen der k. k. geol. Reichsanstalt*, No. 2, 1899, some results of recent geological work in southern Dalmatia are described by G. Bukowski. In the region examined, the tectonic relations were found to be of a very complex character, and overfolding and overthrusting have occurred upon an enormous scale. This may be well understood when it is said that the Hallstadt limestones, forming the base of the series observed, are overlain by Cretaceous and older Tertiary rocks, to be followed in turn by Triassic Dachstein-limestone. In places, the Tertiary beds have become completely squeezed out, in which case the Dachsteinkalk rests directly upon the Cretaceous limestones. In the region of southern Pastrovicchio, the upper beds of the *Diplopora*-limestone have yielded a brachiopod-fauna peculiar for its richness in species and individuals of *Spirigera*. In the upper Triassic limestones, a marked change of facies is apparent. The tufaceous complex of the Dzurmani-beds is overlain by rocks having a Hallstadt cephalopod-facies, which yields in turn, in the higher beds, to a coral-reef facies.

To the *Verhandlungen der k. k. geol. Reichsanstalt*, No. 3, 1899, Dr. J. J. Jahn contributes a short paper on the occurrence of moldavite (bouteillenstein) in the pyrope-bearing sands (early Diluvial) of northern Bohemia. After describing specimens found at localities west of Trebnitz, the author gives a summary of the results of experiments carried out by Herr Jos. Bareš, who has investigated the behaviour of moldavite when subjected to very high temperatures, with a view to clearing up the question of its origin. From a comparison of the chemical composition and physical properties of serpentine and moldavite, the hypothesis that the latter has had its origin in the former, as held by Helmhacker, derives no support whatever. By experiments carried out with various kinds of glass, and a comparison of the behaviour of these and of moldavite at temperatures ranging up to 1400° C., as also by a comparison of the chemical composition of the respective substances, Bareš obtains strong evidence against the correctness of the theory that bouteillenstein is an artificial product of glass manufacture. Further experiments refute also the hypothesis that moldavite may have been produced, by the aid of volcanic activity, from felspar-bearing rock rich in silica. From a consideration of the form and surface structure of the various specimens, and their behaviour under the highest temperatures, Herr Bareš agrees with Dr. F. E. Suess in recognising the probability of a cosmic origin.

THE May number of the *Zoologist* contains a very interesting account by Mr. Cronwright Schreiner on the recent extraordinary "trek" of Springbuck in the Cape Colony. The vast number in which these antelopes migrated in former years is a familiar fact; but in recent times they were believed to have ceased for ever. All the more remarkable, therefore, is it to hear of the great "trek" which occurred in July 1896. On the occasion when he saw the largest herd, Mr. Schreiner believes that there

were at least half a million antelopes in sight at once; and from this it is inferred that the whole "trek" must have included millions. Of course, thousands of head fell to the rifles of the Boer and other hunters; and a brisk trade sprang up in hides and meat. The writer of the paper infers that a migration on such a scale will never be seen again, for the reason that the Springbuck will be unable to recruit their numbers to a sufficient degree.

WE are asked to announce that the second annual dinner of the Association of Old Students of the Central Technical College will be held on Thursday, July 6.

THE *Quarterly Journal of Microscopical Science* contains two papers by Mr. J. E. S. Moore, dealing with his researches on the Molluscs of the great African lakes, especially Tanganyika. In the first paper, which discusses the morphology of the two littoral forms *Tanganyikia* and *Spekia*, the most interesting relates to the ancestry of the terrestrial *Cyclophoridae*. It is suggested that they trace their origin from some fresh-water derivative of the Tanganyika genus *Purpurina*, such as the cretaceous *Pyrgulifera*, which may represent a fresh-water non-halolimnic development of the type. The second paper deals with the truly halolimnic genera *Nassopsis* and *Bythoceras*. In regard to these and allied types, the author makes the following concluding observations. "We have the wonderful similarity of the halolimnic shells now living in Tanganyika to those which have been left fossilised at the bottom of the old Jurassic seas; and, lastly, there are the morphological characters of the halolimnic animals themselves, whereby they become mentally depicted like nothing so much as the incompletely developed embryos of numerous living oceanic types."

A COPY of volume x. of the *Transactions* of the American Pediatric Society, edited by Dr. Floyd M. Crandall, has been received. A number of papers and reports on infantile diseases are contained in the volume, one of the most important being a statement of the results of the Society's collective investigation on infantile scurvy in North America.

"A Select Bibliography of Chemistry" (1492–1892), by Prof. H. Carrington Bolton, was published in 1893. The first supplement of this volume, including words omitted in the previous volume, and bringing the literature of chemistry down to the close of the year 1897, has just been issued as No. 1170 of the Smithsonian Miscellaneous Collections. The sections into which the titles are grouped are: bibliography, dictionaries, history, biography, chemistry (pure and applied), and periodicals, the titles being in each case arranged alphabetically according to authors. The section dealing with alchemy has been dropped. The number of titles in the original volume was 12,031, and the number in the present volume is 5554, making a total of 17,585. Germany comes first in the number of additional titles, with a total of 1461. France follows with 1085 titles, England with 972, and Russia with 581 titles. The next six countries in order of their number of contributions to chemical literature are: Iceland, 434; Sweden, 196; Holland, 191; Denmark, 151; Portugal, 123; Bohemia, 98.

A COMMENDABLE characteristic of the report of the Marlborough College Natural History Society is a collection of anthropometrical particulars referring to boys in the school, obtained by Mr. E. Meyrick. The measurements are a continuation of records published last year. For each boy the information tabulated is his form, age, height, weight, size of chest expanded and contracted, and where possible the increase compared with last year's measures. Information of this kind is of real service to students of physical anthropology. Among other noteworthy matters in the report is a list of 417 wild flowering plants observed by members of the botanical section, one member, Mr. F. E. Thompson, having obtained no less than 189, a worthy conclusion on his part to a series of botanical observations extending over thirty years. Appended to the usual meteorological statistics for every day of 1898 is a summary of the meteorology of Marlborough for the ten years 1889–1898. In addition, the report contains sectional reports, notes and observations, notes on lectures, and a variety of other information—all instructive and of interest as showing the development of the scientific spirit in a public school.

THE additions to the Zoological Society's Gardens during the past week include a Green Monkey (*Cercopithecus callitrichus*, ♀) from West Africa, presented by Dr. H. Strachan; a Rufous Tinamou (*Rhynchotus rufescens*) from Brazil, presented by Mr. Henry Bell; a Common Kingfisher (*Alcedo ispida*) from Ireland, presented by Mr. Ronald Edwards; two Jackdaws (*Corvus monedula*, white var.), European, presented by Mr. Eardley Wilmot B. Holt; two Secretary Vultures (*Serpentarius reptilivorus*) from South Africa, presented by Mr. J. E. Matcham; two Green Turtles (*Chelone mydas*) from the Gulf of Manor, presented by Captain Geo. G. C. Stevenson; two Black-striped Wallabies (*Macropus dorsalis*, ♂ ♀) from New South Wales, two Stonechats (*Pratincola rubicola*) from South of France, two Derbian Parrakeets (*Palaeornis derbyana*) from China (?), a South Albemarle Tortoise (*Testudo vicina*) from South Albemarle Island, deposited; a Musk Duck (*Biziura lobata*) from Australia, three Barbary Turtle Doves (*Turtur risorius*) from Africa, a Tuatera Lizard (*Sphenodon punctatus*) from New Zealand, purchased; two Collared Fruit Bats (*Cynonycteris collaris*), born in the Gardens.

## *OUR ASTRONOMICAL COLUMN.*

COMET 1899 *a* (SWIFT).—

*Ephemeris for 12h. Berlin Mean Time.*

| 1899. | R.A. h. m. s. | Decl. ° ′ | Br. |

Being now almost two months past perihelion, the comet is rapidly becoming less conspicuous. During the week it will pass from Herculis into Bootis, its path being nearly parallel to a string of 4th mag. stars $\phi$ and $\chi$ Herculis, $\mu$, $\delta$ and $\epsilon$ Bootis.

## *THE ROYAL OBSERVATORY, GREENWICH.*

ON Saturday last (June 3), the Astronomer Royal presented his Annual Report to the Board of Visitors of the Royal Observatory, Greenwich. The weather was all that could be desired, and the large number of guests, numbering among them Prof. Cornu, was able to comfortably inspect the buildings and instruments, which had as usual been thrown open to view.

The following is a brief *résumé* taken from the report:—

*Buildings.*

The new Observatory building, which has been in progress since 1891, was completed last March, by the addition of the east and west wings. This handsome building provides much needed accommodation for the Observatory staff, for the photo-

graphic records and books of calculations, and for the library, which had long outgrown the rooms hitherto available for it. In the new Observatory building—which is cruciform in shape, having four wings of three stories, with a central tower carrying the Thompson equatorial and dome—the staff occupies the principal floor, the library will be placed in the ground floor of the north, east and west wings, the ground floor of the south wing being fitted up as a workshop, and the upper floor will accommodate the photographic and other records and the stock of publications of the Observatory.

The completion of the new Observatory building, which at three points breaks into the existing boundary fence, makes it desirable that the boundary of the Observatory should be enlarged in order to show off the handsome new building, and a proposal to give effect to this is under the consideration of the Admiralty.

The new Magnetic Pavilion, in an enclosure in Greenwich Park, at a distance of about 350 yards from the Observatory, on the east side, was completed at the end of last September, and the magnetic instruments for absolute determinations have been installed there. The greatest care has been taken to exclude all iron in building the Magnetic Pavilion, and the site has been selected so that there is no suspicion of magnetic disturbance from iron in the neighbourhood. The enclosure also provides a good meteorological station, where the standard thermometers and rain-gauges have been mounted.

*Transit Circle.*

The sun, moon, planets, and fundamental stars have been regularly observed on the meridian as in previous years. The number of observations made from 1898 May 11 to 1899 May 10, was as follows :—

| | |
|---|---|
| Transits, the separate limbs being counted as one observation ... ... ... ... | 11,764 |
| Determinations of collimation error ... ... | 298 |
| Determinations of level error ... ... ... | 694 |
| Circle observations ... ... ... ... | 10,830 |
| Determinations of nadir point (included in the number of circle observations) ... ... | 665 |
| Reflection observations of stars (similarly included) ... ... ... ... ... | 560 |

The number of stars observed in 1898 was about 5000.

The number of meridian observations in the first three months of 1899 was unusually large, being 1200 more than the average of the three preceding years. The excess was entirely in January and February, for which months the number of observations was double the average number. This unusually large number of observations has caused great pressure on the computing staff in that branch, and it is much to their credit that the reductions have fallen so little behind.

The apparent correction for discordance between the nadir observations and stars obtained by reflection for 1898 was found to be $-0''{\cdot}36$. The results of recent years are as follows :—

| | Mean | Range |
|---|---|---|
| 1880–1885 | $-0''{\cdot}34$ | from $-0''{\cdot}29$ to $-0''{\cdot}45$ |
| 1886–1891 | $+0{\cdot}03$ | from $-0{\cdot}12$ to $+0{\cdot}09$ |
| 1892–1898 | $-0{\cdot}30$ | from $-0{\cdot}25$ to $-0{\cdot}36$ |

New steel screws for the microscope micrometers were introduced in 1886, and in October 1891 the object-glass was repolished, and a new steel telescope micrometer screw was introduced.

Both microscope and telescope micrometer screws have been examined, but show no errors which would account for this discordance.

The co-latitude of the transit-circle, as found from observations of about 600 stars in 1898, is $38^\circ\ 31'\ 21''{\cdot}75$, differing by $-0''{\cdot}15$ from the adopted value. The effect of Chandler's latitude variation was computed for each of these stars within the limits $10^\circ$ and $35^\circ$ N.P.D. The table, which is given in the Report, exhibiting the effect of Chandler's correction to the colatitude on the means of groups arranged for each hour of right ascension, shows how entirely its influence is eliminated from the resulting co-latitude.

The mean error of the moon's tabular place (computed from Hansen's lunar tables with Newcomb's corrections) is $-0{\cdot}143$s. in R.A. and $+0''{\cdot}14$ in N.P.D. deduced from 104 observations. These are equivalent to an error of $-2''{\cdot}23$ in longitude and $+0''{\cdot}21$ in ecliptic north polar distance.

In the last Report, the equivalent error in longitude was $-1''{\cdot}97$ and $+0''{\cdot}16$ in ecliptic north polar distance.

From June to December 1898 a new determination of the division errors of the transit-circle was made by Mr. Dyson and Mr. Thackeray. An account of this investigation has been published in the *Memoirs* of the R.A.S., vol. liii., so that we need not refer again to it here.

*The New Altazimuth.*

After the date of the last Report, it was found that the readings of the several microscopes varied systematically with the direction in which the instrument was swung. As this pointed to a constraint in the axis, several modifications were made in different parts of the instrument. These various changes were not completed till February 23, and since then the observations, both of transits and zenith distances in reversed positions, show a satisfactory accordance.

Among the observations made with this instrument may be mentioned 1017 R.A. observations of the sun, planets and stars, 961 N.P.D. observations of the same bodies, and 20 observations in R.A. and N.P.D. of the moon.

*Thompson Equatorial.*

The return of the object-glass of the 26-inch refractor on 1898 May 16 is referred to in the last Report. Slight figuring of the outer surface under Sir Howard Grubb's direction was continued till June 8. The object-glass was further tested by photographs taken inside and outside of focus and with diaphragms, and was finally approved in September. The new 30-inch mirror, of slightly shorter focal length (corresponding to the length of the tube), was received from Dr. Common on September 1. Photographs to test the mirror were taken in the principal focus and also in the secondary focus, and it was found to be quite satisfactory.

With the 26-inch refractor, twelve successful photographs of Neptune and its satellite have been obtained, using the occulting shutter to screen the planet during the greater part of the long exposure necessary to show the satellite, a series of short intermittent exposures for the planet being given by lifting the arm of the shutter. The results of these observations are given in the *Monthly Notices of the Royal Astronomical Society*, vol. lix., May. Forty-two successful photographs of sixteen double stars have also been obtained, including six of Aldebaran, for which the occulting shutter was used in order to obtain measurable images of Aldebaran and the faint companion, for which a 20m. exposure was required. A few photographs of fields of stars have also been obtained.

With the reflector, thirty-two photographs of the planet Eros were obtained between September 20 and March 31, nine photographs of Neptune and its satellite, four of Comet Brooks, and one of Comet Tuttle. To investigate the distortion of the field, five photographs of the Pleiades have been taken.

With an exposure of an hour, a "fine photograph of the Andromeda nebula has been obtained."

*28-inch Refractor.*

This instrument has been used throughout the year for micrometric measurements of double stars. Four hundred and ten stars have been measured; 206 of these have their components less than $1''{\cdot}0$ apart, and 87 less than $0''{\cdot}5$. The stars the distance apart of which is less than $1''{\cdot}0$ have been measured on the average on three nights each, and the wider pairs on two and a half nights. The wider pairs measured consist of stars in which there is a considerable difference of magnitude between the components, of third companions to close pairs, and of stars which are of special interest.

A long series of measures of 70 Ophiuchi has been obtained.

*Astrographic Equatorial.*

During the year ending 1899 May 10, 465 plates have been taken on 120 nights. Of these 78 have been rejected, viz. 34 because the exposure was interfered with by cloud, or because the images were too faint to show 9th magnitude stars with a 20s. exposure; 17 owing to faults in guiding or exposure; 8 on account of wrong setting; and 19 from miscellaneous defects.

The following statement shows the progress made with the photo-mapping of the heavens :—

| | For the Chart (Exposure 40m.). | For the Catalogue (Exposures 6m., 3m., and 20s.). |
|---|---|---|
| Number of photographs taken | 256 | 200 |
| ,, successful plates | 211 | 167 |
| ,, fields photographed successfully | 206 | 160 |
| Total number of successful fields reported 1898 May 10 | 828 | 909 |
| Number of photographs, previously considered successful, rejected during the year | 7 | 39 |
| Total number of successful fields obtained to 1899 May 10 | 1027 | 1030 |
| Number still to be taken | 122 | 119 |

Of the 122 fields to be photographed, 101 are within 7° of the pole. The photography of this part of the sky was purposely deferred till near the epoch 1900, and has just been begun.

In last year's Report, we mentioned that 166 catalogue plates out of 909—that is, nearly one-fifth of the total number—and 90 chart-plates out of 828, had deteriorated owing, probably, to the effect of damp in the building in which they have to be stored pending the completion of the new physical laboratory.

This year we read that the deterioration of some of the plates has continued, as it was not found practicable to move the photographs into the new Observatory building till March. Besides the plates which have been rejected during the year, as mentioned in the tabular statement above, there are about forty catalogue plates in the zones yet to be measured which should be taken again. The damaged chart-plates have all been copied, and the positives on glass will in any case be available. But it seems advisable that all the damaged plates, whether measured or copied, should be replaced by others, and, as the photo-mapping for the zone allotted to Greenwich is now nearly completed, this work can shortly be taken in hand.

*Heliographic Observations.*

In the year ending 1899 May 10, photographs of the sun have been taken on 195 days, either with the Dallmeyer or Thompson photo-heliographs. The former, mounted on the terrace roof of the south wing of the physical observatory, was used as the regular instrument for solar photography up to and including 1898 July 27, when the Thompson 9-inch photo-heliograph was substituted for it. The Dallmeyer photo-heliograph was dismounted and placed in the upper floor of the museum on 1898 October 13. Of the photographs taken with either instrument, 394 have been selected for preservation, besides sixteen photographs with double images of the sun, for determination of zero of position-angle. Photographs to supplement the Greenwich series have been received from India and Mauritius up to 1899 January 13.

For the year 1898, Greenwich photographs have been selected for measurement on 165 days, and photographs from India and Mauritius (filling up the gaps in the series) on 192 days, making a total of 357 days out of 365 on which photographs are at present available. No photographs have been received from Mauritius of later date than 1898 August 7, and as the eight days which are at present unrepresented are all since that date, it is possible that the record for the year may yet be rendered complete.

The chief incident in the history of the sun's surface, during the period covered by this Report, was the very remarkable temporary revival of activity which set in at the end of July and lasted almost to the middle of November, culminating in the appearance of the great group of September 3–15. Apart from this, the sun's surface has been very quiet during the year, the spots being few, isolated, and small. There have, however, been no such long-continued instances of the entire absence of spots as to suggest that the minimum had been actually reached or is immediately at hand, the number of days without spots for which a record is at present available being 49, as compared with 42 in the previous Report.

*Magnetic Observations.*

The variations of magnetic declination, horizontal force, and vertical force, and of earth currents, have been registered photographically, and accompanying eye observations of absolute declination, horizontal force, and dip have been made as in former years.

On the completion of the new Magnetic Pavilion, last September, the Gibson deflection instrument and the Airy dip-circle were mounted there, and regular determinations of magnetic horizontal force and dip have been made there from that time.

The principal results for the magnetic elements for 1898 are as follows:—

| | | |
|---|---|---|
| Mean declination | | 16° 39'·2 West. |
| Mean horizontal force | | 3·9878 (in British units). 1·8387 (in Metric units). |
| Mean dip | January to June | 67° 12'·4 (with 3-inch needles). |
| | October to December | 67° 11'·3 (with 3-inch needles). |

These results depend on observations on the site of the Magnetic Pavilion, and are free from any disturbing effect of iron. The correction to the declination, as found in the Magnet House, is −10'·7, deduced from the observations with the Elliott declinometer, in September and October, and with the new declinometer in the Magnetic Pavilion, the values found with the two instruments being precisely the same.

The question of the protection of the Observatory from disturbance of the magnetic registers by electric railways or tramways in the neighbourhood has caused much anxiety during the past year. A number of such railways are now projected, and the value of the magnetic registers, which have now been carried on continuously for nearly sixty years, will depend entirely on the conditions under which electric traction is used. Steps have been taken, in concert with Prof. Rücker, acting on behalf of Kew Observatory, to have a special clause inserted for the protection of Greenwich and Kew Observatories. This has already been accepted in several cases, and it is hoped that it will be agreed to in others where necessary.

*Meteorological Observations.*

The mean temperature of the year 1898 was 51°·3, being 1°·8 above the average for the fifty years 1841–1890. During the twelve months ending 1899 April 30, the highest daily temperature in the shade recorded in the open stand was 92°·1 on September 8. The highest reading recorded in the Stevenson screen was 90°·0 on the same day.

The monthly mean temperatures were in excess of their corresponding averages from August to February (inclusive) to the mean amount of 3°·9. In December, the excess amounted to 6°·1, and in September to 4°·9. In the five remaining months of the year the mean temperatures were below the average values.

The mean daily horizontal movement of the air in the twelve months ending 1899 April 30 was 291 miles, which is ten miles above the average for the preceding thirty-one years. The greatest recorded movement was 950 miles on January 21, and the least 67 miles on March 14. The greatest recorded pressure of the wind was 33 lbs. on the square foot on February 13, and the greatest hourly velocity 53 miles on January 12.

The number of hours of bright sunshine recorded during the twelve months ending 1899 April 30 by the Campbell-Stokes instrument was 1500 out of the 4454 hours during which the sun was above the horizon, so that the mean proportion of sunshine for the year was 0·337, constant sunshine being represented by 1.

The rainfall for the year ending 1899 April 30 was 22·74 inches, being 1·80 inches less than the average of fifty years. The number of rainy days was 158. The rainfall in the month of September amounted to 0·305 inch, being the smallest September rainfall on record in the period 1841–98, with the exception of September 1865, when the rainfall was only 0·16 inch.

*Longitude of Killorglin.*

The longitude of Killorglin, at the head of Dingle Bay, Ireland, was determined in October and November. The station was selected in order to eliminate, as far as possible, the effect of local attraction at Valentia and Waterville, both of which longitude stations are situated between the Atlantic on the west and a mountain mass on the east.

A desire has been expressed by the International Geodetic Association for a re-determination of the longitude of Paris—Greenwich in view of the discordance in the results found by the French and English observers respectively in the two de-

terminations in 1888 and 1893, and the Council of the Paris Observatory have recommended that this work should be undertaken in concert with Greenwich Observatory. As a preliminary to the actual longitude operations, it seems essential that the instruments to be used by both parties of observers should be thoroughly tested at contiguous stations.

## SPURIOUS EARTHQUAKES.

IN compiling the seismic record of any country, we are liable to errors from two sources. We cannot help omitting a large number of slight earthquakes, which it is difficult to separate from the countless tremors that are artificially produced. On the other hand, we include a smaller, but still important, number of shocks which are not seismic in their origin, though they simulate earthquakes in many ways. Errors of the former class are, of course, difficult to prevent, though they tend to become less frequent when attention is given to the subject. Those of the latter class may sometimes be eliminated by a study of the different kinds of disturbance which have been, or might be, mistaken for true earthquakes.

The majority of spurious earthquakes in this country are produced by the firing of heavy guns, the bursting of meteorites, and the fall of rocks in underground channels. Explosions and landslips produce disturbances which are at first frequently mistaken for earthquakes, but their real origin cannot fail to be soon discovered and remembered. Perceptible tremors are also produced in buildings by thunder, but it is improbable that permanent errors can thus arise, for the long duration of the sound, in conjunction with the small area affected, provides a simple test. I shall, therefore, confine myself to the first three causes mentioned in this paper.

### FIRING OF HEAVY GUNS.

The sound and tremor produced by the firing of heavy guns are sometimes perceived at great distances; but, as I propose to deal with this subject in another paper, I will merely mention here that observations of the sound at distances exceeding one hundred miles are by no means uncommon.

On two or three occasions within the last few years I have been able to trace supposed earthquakes to this source. On the first (January 7, 1890), two shocks were felt in the southwest of Essex at 12.30 and 1.25 p.m. All the places from which I received accounts lie close to a line running north-east from Woolwich, with one exception, in which the direction is north by east. I have no report of the direction of the wind in the immediate neighbourhood, but southerly and southwesterly breezes were generally prevalent over the whole country on that day. Near the boundary of the district affected, the disturbance was supposed to be seismic by observers who felt the Essex earthquake of 1884: somewhat nearer the origin, the sound resembled the report of a heavy gun; while, six miles from Woolwich, the noise and shock were referred without hesitation to their true cause, the discharge of a 110-ton gun at Woolwich at the times mentioned.[1]

On May 5-6, 1893, a number of shocks were felt at nearly regular intervals in the Isle of Man. At Douglas, where they were very slight, they were regarded as earthquakes; further south, at and near Castletown, they were described as resembling the reports of heavy guns, but the likeness was not striking enough to raise doubts as to their seismic character when it was once asserted; at the Chickens Lighthouse, off the extreme southern point, the keeper informed me that no earthquakes were felt, but that there must have been some man-of-war practising to the south-south-west; and this, on inquiry at the Admiralty, was found to have been the case, H.M.S. *Neptune*, a first-class battle-ship, having been engaged in heavy-gun practice to the south of the island during the very times when the reported earthquakes were heard and felt.

*Tests.*—The principal tests by which the true character of these disturbances may be distinguished are the following: (1) When several are noticed on one day, they are of not very unequal intensity, and may occur at nearly regular intervals. (2) The disturbance is apparently communicated through the air. (3) The gradually increasing confidence in one direction with which the shocks are attributed to gun-firing is no doubt the most important test. (4) In many cases, the position of the disturbed area or the time of occurrence may lead to suspicions regarding the seismic nature of the shocks. (5) If the disturbed area were extensive, a few good time-observations would give a velocity approximating to that of sound-waves in air.

[1] The supposed earthquake at Chelmsford on January 7 (NATURE, vol. xli., 1890, p. 369).

### THE BURSTING OF METEORITES.

The explosive bursting of meteorites is one of the commonest causes of spurious earthquakes. The mistake in such cases, it is probable, arises not so much from any close similarity between the two phenomena, as from the exclusion in the minds of the reporters of all artificial causes, and the consequent inference of a seismic origin. The explosion of a large meteor, weighing one or several tons, on entering the atmosphere is heard, according to the late Prof. H. A. Newton, for "a hundred miles around, shaking the air and the houses over the whole region like an earthquake." (NATURE, vol. xxxiv., 1886, p. 533). Many such cases might be quoted, and a very large number must be known to those who have made a special study of the subject, but the following are probably sufficient for the present purpose.

*West of England Meteorite*, January 25, 1894.—At an early stage of its flight, this meteor, according to Mr. Denning, passed over Chester at a height of fifty-eight miles. It travelled in a direction from N.N.W. to S.S.E., passing almost over Droitwich and Worcester, at a height of about twenty-three miles, and disappearing with an explosion when about sixteen miles above a point four miles north of Ashchurch (near Tewkesbury). Two minutes after its disappearance three detonations were heard at Worcester, "the last being of exceptional violence, shaking buildings and causing the earth to vibrate." At Brinscombe (near Stroud), about a minute or a minute and a half after its disappearance, "there came (apparently from the north-east) a series of explosions, which sounded . . . like a number of field-pieces fired in rapid succession, followed by a volley of musketry." One of the most interesting observations from the present point of view is that made by an observer at Parkfields (near Ross). "A slight earthquake," he says, "was felt here. . . . I heard a loud rumbling noise like an explosion, lasting two or three seconds, which I took for thunder. A young lady who had just gone up to her room tells me that there were two slight shocks, the motion being similar to that of a steamer at sea. . . . I am informed that it was accompanied by a lurid light, which lasted some time, and that objects at a considerable distance were plainly visible. The night was dark and cloudy, with some rain." The recorded observations are too few in number to determine the boundaries of the sound-area and disturbed area, but a perceptible tremor was felt at Alvechurch (near Redditch), which is thirty-nine miles from Ross, and the sound was heard at Alvechurch and Brinscombe, places which are forty-four miles apart.[1]

*Central England Meteorite*, November 20, 1887.—At about 8.20 a.m. a loud sound, accompanied in many cases by a distinct trembling or shaking of houses, was heard over a large area, chiefly in the counties of Cambridge, Bedford, Hertford, Buckingham, Oxford and Berkshire. Many observers at once attributed the phenomena to an earthquake, and Mr. H. G. Fordham, who has made a careful study of them,[2] commenced his inquiries under that impression. It soon appeared, however, that the disturbance proceeded from the air rather than from the ground, and this fact, together with the actual observation of a meteor at the time mentioned, placed its true origin beyond doubt.

The accompanying map is, in part, a reproduction of that prepared by Mr. Fordham; but my object being somewhat different from his, I have added some details and omitted others. Every place where the sound was heard without any mention being made of an accompanying tremor is denoted by a small cross. If the concussion was strong enough to make doors, windows, and other loose objects rattle, the place of observation is shown by a large dot; if the tremor only is mentioned, without any other indication of its intensity, it is marked by a small dot. The sound-area as thus drawn is about 105 miles in length and nearly forty miles in breadth.

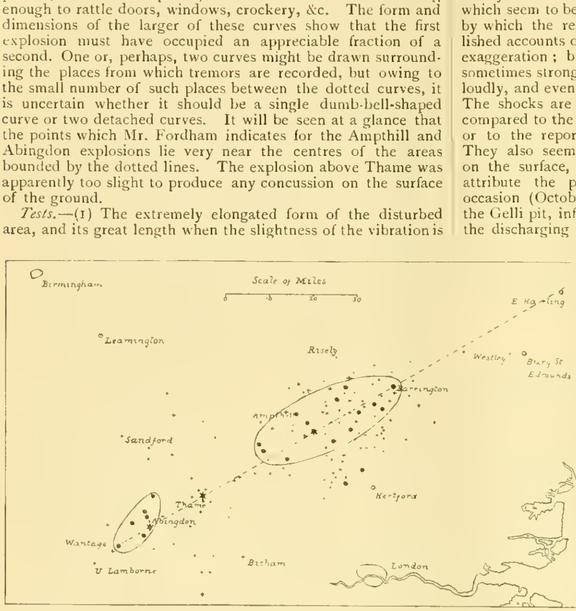
From the grouping of the places, where the sound was especially loud and definite, Mr. Fordham believes that the track of the meteorite would probably be best defined by a line drawn from Barrington (near Cambridge) to Wantage. Assuming this line

[1] NATURE, vol. xlix., 1894, pp. 324-325; *The Times*, January 29, 31, 1894.
[2] The meteorite of November 20, 1887.—*Hertfordshire Nat. Hist. Soc. Trans.*, vol. v., 1888, pp. 33-62.

to be correct, the observation of the meteor from Hertford would show that it was first seen when at a height of about thirty miles above East Harling, in the south of Norfolk, and that when above a point (indicated on the map by a star) about south-east of Ampthill, an explosion occurred which broke off part of the crust of the meteorite. At two other points (also marked by stars) in the neighbourhoods of Thame and of Abingdon and Wantage, explosions seemed to have occurred, the latter terminating the course of the meteorite.

Some additional evidence is furnished by the grouping of the places where the sound of the explosion was accompanied by a distinct tremor. The two dotted curves on the map bound all places (with two exceptions) where the concussion was strong enough to rattle doors, windows, crockery, &c. The form and dimensions of the larger of these curves show that the first explosion must have occupied an appreciable fraction of a second. One or, perhaps, two curves might be drawn surrounding the places from which tremors are recorded, but owing to the small number of such places between the dotted curves, it is uncertain whether it should be a single dumb-bell-shaped curve or two detached curves. It will be seen at a glance that the points which Mr. Fordham indicates for the Ampthill and Abingdon explosions lie very near the centres of the areas bounded by the dotted lines. The explosion above Thame was apparently too slight to produce any concussion on the surface of the ground.

*Tests.*—(1) The extremely elongated form of the disturbed area, and its great length when the slightness of the vibration is taken into account; the detached isoseismal lines in those cases where there are two or more explosions. (2) The sound is far more prominent than the vibration, which is never the case all over the disturbed area of an earthquake unless that area is a very small one; also, the sound-area overlaps the disturbed area on all sides, and this is only the case with very weak earthquakes. (3) The character of the sound, often consisting of a series of explosions. (4) The obvious transmission of the sound-vibrations through the air. Though I have examined many thousands of earthquake-records, the sound is almost uniformly described by the writers as of underground origin. (5) The vibration of doors, windows, &c., is evidently a concussion due to the impact of air-waves. Occasionally a tremor is actually felt, but, as in the case of a heavy thunder-clap, this is no doubt due to the same cause. (6) The evidence of barograms may be useful in those cases where there is reason to believe that the movement is not due simply to the disturbance of the recording arm. (7) The actual observation of the meteor, or, if the sky be covered, of the glare of its light through the clouds.



### ROCK-FALLS IN UNDERGROUND CHANNELS.

The fall of rock-masses in underground channels was for long regarded with favour as a possible cause of earthquakes.[1] No great and widely-felt shock would now be attributed to such a cause, but there are certain local earth-shakes which may reasonably be accounted for in this manner. The fall of a heavy mass of rock is evidently capable of producing the observed effects such as are described below. For example, towards the close of last century, one or more of the great upright stones of Stonehenge suddenly fell. According to Mallet, "the shock felt in all the neighbouring hamlets was so great that for some time, until the cause was discovered, it was thought to have been an earthquake, as in fact it was, though not produced by natural causes."[1]

*Earth-Shakes in the Rhondda Valley.*—In the Rhondda Valley in south-east Wales, there are frequent earth-shakes, which seem to be due to rock-falls in the deserted pit-workings by which the region is honeycombed. In many of the published accounts of these disturbances, there is evidently much exaggeration; but there can be no doubt that the shocks are sometimes strong enough to cause windows and doors to rattle loudly, and even to give rise to a distinct rocking sensation. The shocks are accompanied by a noise which is generally compared to the thud produced by the fall of a heavy body, or to the report of a colliery explosion or a distant gun. They also seem to be felt quite as severely in the mines as on the surface, and alarm the men at work, who naturally attribute the phenomena to an explosion. On a recent occasion (October 16, 1896), a miner, who was working in the Gelli pit, informs me that he heard one loud boom, like the discharging of a shot in rock, followed by a slight rumbling; "but others working in the same pit had a severe shaking, the tools springing off the floor, the dust rising in clouds off the bottom." Again, in the three cases (June 22, 1889; April 11, 1894; and October 16, 1896) which I have studied, the disturbed areas are roughly circular, and the diameters are small, being, respectively, about one, six and three miles in length; and the second of these is said to have been by far the strongest recently felt in the district. The centres of the three areas are close together, the two extreme ones being five miles apart, and they follow roughly the line of the Rhondda Valley. Now, the rapid diminution in intensity from the centre outwards implies a very shallow focus; the shock and sound are by nature such as would be produced by the fall of a heavy mass of rock, underground passages exist at no great depth, and subsidences at the surface are known to occur, for houses have been destroyed in this way in many parts of the district. The evidence in favour of the view that the so-called earthquakes are spurious is therefore strong; but the crucial test, that of finding the fallen mass, has, so far as I know, never yet been satisfied.

*Earth-Shakes at Sunderland.*—A similar, though less artificial, origin may be urged with equal force for the remarkable series of earth-shakes which are occasionally felt in and near Sunderland. These have been described and the theory of their origin clearly worked out in an admirable paper[2] by Prof. G. A. Lebour, from which the following details are taken. The disturbances consist of sudden shakes, strong enough to make crockery and windows rattle, often, but not always, accompanied by loud noises and dull rumbles. They are, moreover, singularly local, being almost entirely confined to the south-west part of the town, and, apparently, to certain linear bands within that part. As in the case of the Rhondda Valley shocks, the foci must be situated at slight depths, and the phenomena are such as would result from underground rock-falls. It is also certain that the necessary channels exist, for the magnesian limestone, on which Sunderland is built, is simply riddled with cavities of every size and shape, the origin of which is not far to seek. In the midst of the hardest and most compact portions of the limestone, there occur masses of soft pulverulent earthy

[1] I need not do more than refer to the subsidences in certain well-known districts which are almost entirely undermined by coal-pits or brine channels. The disturbance is sometimes described as resembling a severe earthquake, but there could hardly be more than a momentary confusion between the two phenomena.

[1] *Roy. Irish Acad. Trans.*, vol. xxi., 1848, p. 63.

[2] "On the Breccia-Gashes of the Durham Coast and some Recent Earth Shakes at Sunderland." (North of England Inst. of Min. Eng. *Trans.* vol. xxxiii., 1884, pp. 165–174.) See also *Geol. Mag.*, vol. ii., 1885, pp. 513–515.

matter, which are readily removed by the mechanica action of percolating rain-water. In such naturally-formed gullets run the feeders of water that are met with in sinking through the magnesian limestone, and these feeders, by chemical action, must cause much additional destruction of the rock. Quite apart from the water which runs off into the sea, that which is pumped up annually by the local water company is estimated to contain lime and magnesia in solution corresponding to nearly forty cubic yards of solid rock.

It seems evident that masses of rock must from time to time fall from the roofs of channels so formed. But we are not here left entirely to conjecture, for, at numerous points along the Durham coast, sections of such channels are exposed that are entirely filled up by angular fragments of the very rock which forms the cliff, and bound together by a cement of the same material. The "breccia-gashes," as they have been termed by Prof. Lebour, vary in width from a few feet to many yards; they are almost invariably narrow at the bottom, and generally wide at the top. "In some cases the broken fragments within the fissures can be traced graduating through semi-brecciated portions of beds to wholly undisturbed strata in the walls or fissure-cheeks. When the top of a fissure is exposed in section, the breccia is also seen usually to pass gradually upwards, first into semi-brecciated matter, and finally to undisturbed or only slightly synclinal beds bridging over the mass of broken rock. When the entire transverse section of a fissure is exposed, it is seen to be a deep V-shaped ravine or gullet, tapering to a point below, and the rocks below it are wholly undisturbed" (p. 166).

*Tests.*—Individual spurious earthquakes belonging to this class are the most troublesome of all to investigate, for, in most cases, we have to rely on circumstantial evidence alone. The principal tests will be obvious from the above descriptions. They are: (1) the small disturbed area and the comparatively great intensity near its centre; (2) the nature of the shock and sound; (3) the known or inferred honeycombed structure of the district, and the occurrence at other times of subsidences at the surface.

Charles Davison.

## REPORT OF THE LONDON TECHNICAL EDUCATION BOARD.

The annual report of the Technical Education Board of the London County Council was recently presented to the Council. The following paragraphs of the report, referring to the Board's relations with the Department of Science and Art and with the new London University, are abridged from the *Technical Education Gazette.*

### *Relations with the Department of Science and Art.*

The Council has been recognised by the Department of Science and Art as the local authority responsible for science and art instruction within the area of the County of London in accordance with Clause VII. of the Science and Art Directory. The powers and duties which such recognition may give have been delegated by the Council to the Board in the same way as the powers conferred by the Technical Instruction Acts were delegated. Ever since the passing of the Technical Instruction Act in 1889, the Science and Art Department has been in the position of the central authority for technical instruction, and the county councils and county borough councils have been in the position of local authorities for technical instruction. Clause VII. introduced a certain readjustment of duties as between the central authority and the local authorities. No new powers are conferred outside the provisions of the Technical Instruction Acts, but the clause provides for some of the functions under those Acts which have hitherto been discharged by the central authority being delegated to the local authority. Over thirty counties and county boroughs have availed themselves of the clause, and it is stated by those who have had experience of the working of the new system that it is advantageous both to particular schools and to the district generally.

The principal benefits which the Board anticipates from the working of Clause VII. in London are the following:—

(*a*) Increased facilities for coordinating and organising science and art work in accordance with the particular needs of each locality.

(*b*) Greater regularity and promptitude in the payment of the grants earned on the Department's examinations.

(*c*) Increased opportunities for urging upon the Department such modifications in their courses of instruction as may be specially required by the circumstances of London schools and institutions.

The Technical Instruction Act of 1889 affords, perhaps, the first legislative example in educational work of adaptation to special local requirements. In the definition of technical instruction the Act includes "any other form of instruction (including modern languages and commercial and agricultural subjects), which may for the time being be sanctioned by that Department [the Department of Science and Art] by a minute laid before Parliament and made on the representation of a local authority that such a form of instruction is required by the circumstances of its district." The Technical Instruction Act having provided for the creation of powerful and disinterested authorities for the conduct and supervision of technical instruction over large areas, Parliament, in the words quoted above, expressed its willingness to give to these authorities an important part in determining the particular field of education which should come within their influence, thus enabling both the matter and the manner of education to be adapted to local needs. It is reasonable to suppose that the same principle will now apply in connection with the subjects of technical instruction which are defined by detailed syllabuses in the Science and Art Directory. The Department has already expressed its willingness to meet the wishes of the local authorities in respect of several administrative details.

### *The New University of London.*

In order to formulate the Board's views with regard to the new University, a special sub-committee was last year established for the purpose of investigating the whole subject and reporting to the Board as to the steps which might be deemed necessary for making representations to the Commissioners on any points in which the Board might be specially interested. In pursuance of this policy, the Board forwarded to the Commissioners an expression of its views upon certain matters. In particular, the Board urged upon the Commissioners the desirability of recognising separate faculties for engineering and for economic and commercial science. The Board's representations were supported by similar expressions of opinion from other quarters, and the Commissioners have come to the decision to adopt the policy which the Board favoured. In the draft statutes which they have prepared for the new University, they have decided to provide for (*a*) a special faculty of engineering, and (*b*) a special faculty of economics and political science (including commerce and industry). There is little doubt that the establishment of these faculties will give considerable encouragement to the technical and commercial work in which the Board is specially interested. Recognising the importance of developing the higher departments of these branches of study, the Board has undertaken to allocate to the University out of the funds from time to time placed at its disposal by the Council an annual sum of 2500*l*. towards the maintenance of the faculty of engineering in the new University, and a further sum of 2500*l*. towards the maintenance of the faculty of economics and political science (including commerce and industry), on condition that satisfactory arrangements are made in the constitution of the University with regard to evening students, and the recognition and admission to th several faculties of duly qualified teachers in the polytechnics.

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Oxford.—The following is the speech delivered by the Public Orator, Dr. W. W. Merry, on the occasion of his presenting Dr. R. Trimen, F.R.S., for the honorary M.A. degree on May 16:—

Praesento vobis Ronaldum Trimen, Societatis Regiae Socium, nuper autem Societatis Entomologicae apud Londinium Praesidem. Vir insignis, qui notitiam suam officiosissime impertiendo de Universitate Oxoniensi optime meruit, diu in Africa australi est commoratus, non utique ut gemmas et aurum fodinis erueret neque ut cum Batavis litem sereret, sed ut Naturae arcana altius scrutaretur ac praesertim insectorum inexploratas consuetudines patefaceret.

"In tenui labor, at tenuis non gloria."

Quotus enim quisque mirum illud ingenium quo Natura inermes bestiolas instruxerit vel diligentius investigavit vel exposuit

luculentius? Quis clarius illustravit raram sollertiam qua minuta animalium genera, vel ut compares alliciant vel ut infestas hostium incursiones arceant, nunc colores mutare, nunc novum aliquod simulacrum assumere, nunc etiam sexum mentiri videantur? Quae quidem omnia si primo visu parvi momenti esse habeantur, eadem, nisi magnopere fallor, oculis subjecta fidelibus et summa accuratione tractata, immane quantum prosunt ad intimas vitae leges enodandas. Quae cum ita sint, haud dubitarem eruditissimi auctoris C. Plinii Secundi verba citare de insectorum corporibus scribentis: "In his tam parvis atque tam nullis quanta vis, quae ratio, quam inextricabilis perfectio! . . . Sed turrigeros elephantorum miramur humeros, taurorumque colla et truces in sublime jactus, tigrium rapinas, leonum jubas, cum rerum natura nusquam magis quam in minimis tota sit; et in contemplatione naturae nihil possit videri supervacuum."

Praesento vobis ornatum et excultum virum Ronaldum Trimen, qui et ipse "Naturalis Historiae Libris" tam laudabile incrementum addidit, ut admittatur ad gradum Magistri in facultate Artium, honoris causa.

CAMBRIDGE.—Mr. W. Chawner, Master of Emmanuel College, is to be Vice-Chancellor during the ensuing academical year.

Mr. R. C. Punnett, of Caius College, has been nominated to occupy the University table at the Marine Biological Laboratory at Plymouth.

The Chemical, Pathological, and Anatomical Laboratories will be open during the ensuing Long Vacation, and a number of special courses of instruction will be given in July and August.

The electors to the new chair of Agriculture are the Right Hon. W. H. Long, Mr. A. E. Shipley, Dr. D. MacAlister, Prof. Liveing, Sir J. H. Gilbert, Prof. Foster, Prof. Marshall Ward, and Sir Walter Gilbey.

IT is satisfactory to know that the value of scientific education and research in agriculture is becoming more and more recognised by foremost agriculturists. Mr. Boyd-Kinnear refers to these matters in a contribution to the *Morning Post*, and to the lack of interest taken in them by British farmers. He points out that a knowledge of the scientific principles of agriculture is of fundamental importance, and that what should be taught in our schools are the sciences on which farming rests—physics, chemistry, mechanics, and the physiology of plants and animals. The sound remark is made that for a farmer to work without this kind of knowledge, is much the same as if a doctor were educated by being shown cases in a hospital before he had learned anything of anatomy or the nature of drugs. In order to know agriculture, it is necessary to understand first of all the elements and the action of the soil and the air, and the operations of life. But all that the most learned in science know of these things is infinitely small compared with the amount that is yet unknown. There is, therefore, urgent need, not only for teaching what is known, but also for learning more. That is, we ought to have both schools where the fundamental sciences which agriculture involves are taught, and also institutions for further research into the secrets yet undiscovered.

Referring to agricultural research stations, Mr. Boyd-Kinnear remarks:—In all countries but England these are provided and liberally maintained by the State. In Germany there are, and have been for the last half-century, no fewer than sixty-seven agricultural teaching and research stations. France has fifty-three, Austria thirty-five, and even Russia has fourteen. The other European States, including countries which we call so backward as Spain and Portugal, have sixty-one among them. The United States have fifty-four, these being supported by the individual States; Canada has several, while Brazil, Japan, and Java have each one! England has—none! none, that is, with State endowment. During the last few years, the County Councils of Sussex, Yorkshire, Bucks, and Durham have established teaching colleges, but without any adequate provision for research. There are also the privately-conducted colleges of Cirencester, Downton, and one or two others, while the half-century of inquiries conducted by Sir John Lawes is deserving of grateful acknowledgment. But isolated and private effort is wholly inadequate to meet the want, or even to direct public attention to it.

## SOCIETIES AND ACADEMIES.

### LONDON.

Royal Society, May 4.—"An Observation on Inheritance in Parthenogenesis." By Ernest Warren, D.Sc., University College, London. Communicated by W. F. R. Weldon, F.R.S.

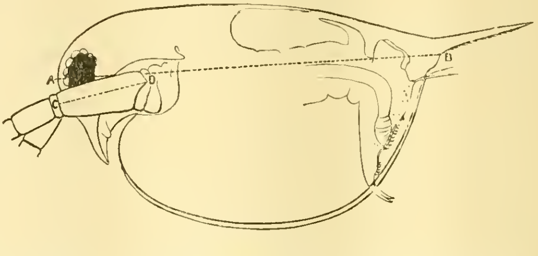
If the hypotheses of Weismann on heredity and variation be founded on fact, then it should follow that offspring produced by parthenogenesis should exhibit little or no departure from their parthenogenetic mother.

It appeared an easy investigation to test this supposition by direct measurement. For this purpose, *Daphnia magna* (Straus) was chosen.

On twenty-three Daphnia, the following measurements were made: (1) the length of the protopodite of the second antenna of the right side (C D see Fig.), and (2) the total length of the body (A B). The first dimension was expressed in thousandths of the second, because these animals (like very many invertebrates) continue to grow throughout life. The broods, amounting in all to ninety-six young, produced by the twenty-three mothers (themselves originating by parthenogenesis), were similarly measured.

The children of the same parthenogenetic family were now seen to vary considerably. A correlation table between the mothers and offspring was prepared, and from it the coefficient of correlation was found to be ·466. The standard deviation (S.D.) of an array of offspring was 5·22 thousandths of the body length: if we express it as a kind of coefficient of variation

we have $\dfrac{\text{S.D. of array}}{\text{Mean of all the offspring}} \times 100 = 3{\cdot}06.$



Thus *in parthenogenesis there is very considerable variability among the offspring*, but whether there is less or more than in sexual reproduction the present measurements do not show.

Dr. Galton and Prof. Pearson have shown that in Basset hounds, stature in man, &c., the correlation between father or mother and offspring approaches the theoretical value ·3, while between mid-parent and offspring it approaches ·424, and the coefficient of regression of offspring on mid-parent is about ·6.

Here, in the Daphnia, the coefficients of correlation and regression were respectively ·466 ± ·054 and ·619 ± ·081. Thus it would *seem* as though in the matter of inheritance a parthenogenetic mother acts as a mid-parent. The subject, however, requires much further elucidation, and the hypothesis is about to be tested on another parthenogenetic animal.

Geological Society, May 24.—W. Whitaker, F.R.S., President, in the chair.—The President called attention to the issue of vol. iii. of Hutton's "Theory of the Earth," and said that the thanks of the Fellows were due to Sir A. Geikie for having edited and annotated most carefully this work. The volume was printed from a previously unpublished manuscript which had been for many years in the possession of the Society: its contents were extremely interesting, and it supplemented the previous volumes by the inclusion of an index to the whole of the work, prepared by Sir A. Geikie.—Prof. Seeley exhibited a cast from a footprint obtained by Mr. H. C. Beasley from the Trias at Stourton. The impression is about 1½ inch long, and nearly as wide. The cast has been treated by oblique illumination, so as to display its osteological structure by means of the shadows thus thrown. All the claws are directed outwards, as in a burrowing animal. The form of the foot

resembles that of a monotreme mammal rather than that of any existing reptile. There appears to be a slender pre-pollex including three bones. The only other example of this structure in the Trias is in the Theriodont reptile *Theriodesmus*, in which it is less definite. This character may add to the interest of other footprints from Stourton, which in the form of the foot approximate to Anomodont reptiles from the Karoo Beds of Cape Colony.—On the distal end of a mammalian humerus from Tonbridge, by Prof. H. G. Seeley, F.R.S. The bone described in this communication was found in 1898 by Mr. Anderson on the bank of the river Medway, near Tonbridge. It was seen projecting from reconstructed rock which contained fragments of flints among other materials. Traces of matrix at the distal end show that the specimen has been derived from quartz-sand bound together with limonite, such as might occur in the Hastings Sand, Wealden Clay, or Lower Greensand. Conditions of mineral structure and osteological character incline the author to believe that the bone was originally contained in the Wealden Clay. The fossil is 4 inches long, and indicates a humerus which may have been 6 inches in length when perfect, as large as that of a wolf but smaller than that of a bloodhound. The form of the shaft precludes any comparison with the carnivora, and indicates a resemblance to ungulate types. When the bone is held vertically and seen from the front, the condyles are oblique—a character not observed in any other animal. The weight of evidence appears to incline towards reference of the fossil to the Artiodactyla, but it probably indicates a new family type.—On evidence of a bird from the Wealden Beds of Ansty Lane, near Cuckfield, by Prof. H. G. Seeley, F.R.S. A fragment of bone found, by Mr. Neville Jones, a member of the London Geological Field Class, embedded in sandstone was identified by the author as probably the distal end of the femur of a bird. The external condyle is not only larger and deeper than the inner, but is more prolonged distally—perhaps the most distinctive avian character of the bone. *Colymbus* is the only existing bird to which the fossil makes any approximation, but the resemblance is distant and not suggestive of near affinity, and it is interesting that the cretaceous birds show so marked an affinity with that type. The resemblances of the dinosaurian and crocodilian femora with this type are such that almost every individual feature of the bone can be paralleled in some fossil referable to these groups, but there are no British dinosaurs of so small a size or possessing some of the marked features shown by this bone.—Notes on the rhyolites of the Hauraki Goldfields (New Zealand), by James Park and Frank Rutley; with analyses by Philip Holland. Part i. of this paper, by Mr. J. Park, gives a description of the rhyolites as seen in the field. After a rest from volcanic action during the secondary period, the tertiary eruptions burst forth and were more widespread than those of recent times. In the Hauraki Peninsula, the basement palæozoic rocks are covered by richly fossiliferous marly clays and limestone of Lower Eocene age, and these by a vast accumulation of andesitic lavas and tuffs, in places 3000 feet thick. These andesites are the gold-bearing rocks of the district, and they are succeeded by rhyolitic lavas and ashes. Both andesites and rhyolites were influenced by solfataric action, resulting in siliceous deposits rich in gold and silver. The rhyolites rest on rocks probably of Upper Miocene age, and are followed by Pleistocene and recent deposits; so that they probably range from older to newer Pliocene in date. Part ii. contains the observations of Mr. Rutley on the petrology of the rhyolites. The rocks present occasional occurrences of perlicity, and the lithoidal types sometimes owe their characters to subsequent devitrification, sometimes to the effect of cooling on, or immediately after, eruption. Reheating has at times reduced the felspars to the condition of felspar-glass. Although plagioclase-felspar is common, the analyses indicate that the series must be retained with the rhyolites, it being quite possible that some of these minerals may have been derived from the andesites.—On the progressive metamorphism of some Dalradian sediments in the region of Loch Awe, by J. B. Hill, R.N. (communicated by Sir A. Geikie, F.R.S.). The region under discussion contains two principal series of rocks, passing one into another without a break, and conveniently referred to the Dalradian System: (1) The Ardrishaig Series (phyllites and fine-grained quartzites). (2) The Loch Awe Series (black slates, limestones, grits, and quartzites). The latter series lies in a gentle trough of the former. Even in their most altered state, the clastic nature of the rocks of the Loch Awe Series is apparent. Both series are pierced by innumerable intrusive sills of epidiorite, hornblende-schist, and chlorite-schist, modified diorites and gabbros, which effect contact-metamorphism in the bordering sediments. Intrusive rocks of post-schistose date also occur, like the Glenfyn granite, the granite of Ben Cruachan, and smaller masses of granite, monzonite, hyperite, ultrabasic rocks, quartz-porphyries, felspar-porphyries, porphyrites, and lamprophyres; these are in their turn cut by dolerite and basalt-dykes. All these rocks exhibit progressive metamorphism when traced towards the north-east and towards the Central Highlands, a character best seen in the loop formed by the rocks near the head of Loch Awe. Although the author does not go very fully into the question of the causes of the progressive metamorphism exhibited in tracing these rocks towards and into the Central Highland schists, he had reason to suspect that "the intense regional type of metamorphism was linked with the same phenomena that afterwards resulted in the irruption of the granite-masses."

### PARIS.

**Academy of Sciences**, May 29.—M. van Tieghem in the chair.—On isothermal surfaces, by M. Gaston Darboux.—On the laws of pressures in guns, by M. Vallier. A theoretical discussion of the distribution of pressure from point to point of the barrel during firing.—On cyclic pencils which contain a system of geodesics, by M. C. Guichard.—On the series of Dirichlet, by M. Lerch.—On the true polarisation of dielectrics placed within an electric field, by M. H. Pellat. The hypothesis is advanced that polarisation is not instantaneous; but that a dielectric, solid or liquid, placed suddenly in an electric field, takes a polarisation which increases with the time, reaching a maximum asymptotically. If the field ceases, the polarisation decreases gradually, becoming zero at the end of a certain time, theoretically infinite. The results of an experimental study are in agreement with this hypothesis.—Polymerisation of abnormal vapours: nitrogen peroxide and acetic acid, by M. A. Leduc. In a previous paper, the author has shown that the variations in the density of chlorine with temperature are in perfect agreement with the theory of corresponding states, and the assumption that a dissociation of chlorine molecules has taken place is unnecessary. An application of the same method to the cases of nitrogen peroxide and acetic acid shows that the molecule is clearly dissociated.—On the measurements, in terms of a wave-length as unit, of a quartz cube, of 4 cm. length of side, by MM. Ch. Fabry, J. Macé de Lépinay, and A. Perot. The measurement was effected by means of the interferential method previously described, the variations between the individual readings being of the order of 1 in 1,000,000.—Bravais points and poles, by M. Pierre Lefebvre.—On the estimation of hydrogen phosphide in gaseous mixtures, by M. A. Joannis. A solution of copper sulphate cannot be employed to estimate hydrogen phosphide in gaseous mixtures, except in the absence of gases absorbable by copper salts. The copper sulphate solution must always be employed in considerable excess.—Separation and estimation of traces of chlorine in presence of a very large excess of bromide, by M. H. Baubigny. The method of copper sulphate and potassium permanganate is employed, and analyses of samples of potassium bromide sold as pure showed that a trace of chlorine was invariably present, 0·1 per cent. of chlorine being the minimum.—Properties of some mixed haloid salts of lead, by M. V. Thomas.—On the quantitative separation of cerium, by MM. G. Wyrouboff and A. Verneuil. The method suggested is based upon the solution of the mixture of oxides in nitric acid, and subsequent polymerisation of the oxide in presence of sulphuric acid. The test analyses given are very satisfactory.—The enantiomorphic structure of *l*- and *r*-benzylidene-camphors as revealed by corrosion figures, by M. Minguin.—Mixed combinations of phenylhydrazine and another organic base with certain metallic salts, by M. J. Moitessier.—Study of some oxymethylenic derivatives of cyanacetic ethers, by M. E. Grégoire de Bollemont.—Centrosome and fecundation, by M. Félix Le Dantec.—On the variations and specific grouping of the American Peripatæ, by M. E. L. Bouvier.—Spontaneous asphyxia and the production of alcohol in the deeper tissues of ligneous stems under natural conditions, by M. Henri Devaux. A study of the respiratory coefficients of the internal layers of certain plant stems showed that the ratio $CO_2/O_2$ increases rapidly with the temperature. This increase of carbon dioxide, according to the

author, can only arise from a true fermentation, and in accordance with this view alcohol was obtained from such stems.—The guidroa, the caoutchouc tree of Madagascar, by M. Henri Jumelle. An examination of the guidroa showed that it clearly belongs to the genus *Mascarenhasia*; but, as it does not exactly agree with any of the fifteen or sixteen species actually known, the name *M. velutina* is proposed for the plant.—On the parasitism of *Ximenia americana*, by M. Edouard Heckel.—On some rhyolites from Somaliland, by M. A. Lacroix.—On the eruptive rocks of Cape Blanc (Algeria), by MM. L. Duparc and E. Ritter. Microscopic and chemical examination of the volcanic rocks of Cape Blanc show them to be neo-volcanic quartz-porphyry of a basic character.—On the existence in the blood of animals of a substance preventing the coagulation of milk, by M. A. Briot. Blood serum from the horse contains a substance capable of neutralising the effects of a certain quantity of rennet. This substance is of a diastatic nature, since it cannot be dialysed, is destroyed by heat, and can be precipitated by ammonium sulphate and by alcohol.

## THE ANTHROPOLOGY OF BADEN.

*Zur Anthropologie der Badener; Bericht über die von anthropologischen Kommission des Karlsruher Altertumsvereins an Wehrpflichtigen und Mittelschülern vorgenommenen Untersuchungen.* By Otto Ammon. Pp. xvi + 707. Maps 15. (Jena: Gustav Fischer, 1899.)

FOR many years the distinguished worker, Dr. Ammon, has been conducting an anthropological survey of the Grand-duchy of Baden in such an exhaustive and detailed manner as cannot fail to excite the admiration of all interested in this branch of science. A considerable proportion of his investigations has been already published and incorporated in anthropological text-books; but the present bulky volume gives the whole of his work in collected form, and embodies such generalisations as he considers can at present be safely attempted. For the final bearings of these investigations on the history and evolution of this portion of the Caucasian race, Dr. Ammon states, however, that further observations are necessary both in his own and in neighbouring countries. As a monument of patient research, many of the fruits of which others will pluck, the volume before us reflects the highest credit on the author and his fellow-worker, Dr. Wilser.

The observations have been carried out on recruits and school-children; the two series being kept quite distinct from one another. The country has been mapped out into districts, which were assiduously worked from 1887 to 1894, three out of the four chief districts having been undertaken by Dr. Ammon himself, while the fourth has fallen to the lot of Dr. Wilser. The number of individuals (which is very great) examined in each of the four districts is clearly indicated on the first of the admirable series of maps, which render both the physical features of the country and the results of the survey conspicuous at a glance. In view of the general gradual numerical diminution of blonds and the increase of brunettes as we pass from North to South Germany, Baden, as forming a long narrow strip running from the south towards the centre of the German empire, is admirably circumstanced to display the development of this law in the southern provinces.

In addition to describing the ordinary physical features of the country, the geological structure is likewise taken into account; and the effects of all natural surroundings on the population are thus considered in full detail. To enumerate all the anthropological features which have entered into the scheme of survey would be wearisome; and it must suffice to say that bodily stature (subdivided into total length, sitting-length, and leg-length), the proportions of the length to the breadth of the head, the colour of the eyes and hair, and the development of hair on parts of the person other than the scalp, are all taken into consideration. Especial attention is directed to the difference in the anthropological features of the inhabitants of the rural and urban districts; and, above all, to the changes in the population of the latter induced by immigration from the former. In these investigations, Dr. Ammon lays claim to having founded a new branch of anthropology.

Seeing that to render adequate justice to the scope of the work would require a considerable portion of a number of NATURE, it will be advisable to concentrate attention on a few features. Among these, the relative prevalence of long-heads and round-heads, of blonds and brunettes, in different districts is perhaps the most generally interesting.

At the commencement of the second section of the work we find some theoretical observations on the three "primitive" types of man met with in Europe. In common with many other modern anthropologists, such as Ripley and Sergi, the author recognises, firstly, the Mediterranean long-heads, of medium or small stature, with dark eyes, hair, and skin. Secondly, the North European long-heads, of tall stature, with blue eyes, blond hair, and fair skin. And, thirdly, the Alpine round-heads, whose stature is medium, with dark eyes, hair, and skin. And here it is important to notice that the author speaks of these simply as *types*, in contradistinction to *races*. He further observes that, owing to crossing, neither of the three types are common in their original purity in any district. In Baden itself, the population at the present day seems chiefly due to a mixture of the fair North European long-heads with the dark Alpine round-heads, the dark Mediterranean long-heads having failed to penetrate so far north in any great numbers.

The following table shows the number of individuals of each type met with among different classes of the population:

| Type. | Rural districts. | Immigrants. Small towns. | Immigrants. Large towns. | Town-born. Small towns. | Town-born. Large towns. |
|---|---|---|---|---|---|
| North European | 146 | 4 | 11 | 27 | 15 |
| Alpine | 26 | 3 | 5 | 3 | 1 |
| Mediterranean | 9 | 0 | 0 | 0 | 0½ |

The percentage from these works out as below:—

| | | | | | |
|---|---|---|---|---|---|
| North European | 1·45 | 0·77 | 1·25 | 1·94 | 2·54 |
| Alpine | 0·39 | 0·93 | 0·91 | 0·35 | 0·27 |
| Mediterranean | 0·09 | 0 | 0 | 0 | 0·08 |

From this we see that, while among the immigrants the North European type is rarer in the small and the large cities than in the rural population, among the town-bred the percentage rises so as to exceed that of the rural districts, this being most markedly the case in the large cities, where we have 2·54 per cent., against 1·45 in the country districts.

Respecting the Alpine type, we find the immigrants into small towns standing at 0·93 per cent., and at 0·91 in the larger cities, as against 0·39 in the rural districts; whereas in the town-bred class the percentage is less than in the country districts, the diminution being most marked in the case of large cities.

Here, therefore, we have evidence that the blond long-heads tend to gravitate towards the large cities, where they flourish; and that while there is also a large immigration of the dark round-heads, yet that these tend to die out in their urban homes. Certain details are also given with regard to the position occupied by the dark round-heads among their fellow-students in the schools; but into these it is impossible to enter on this occasion.

To a certain degree, these results accord with those arrived at by Monsieur de Lapouge in France, that anthropologist contending that the enterprising, restless, long-heads migrate in disproportionate numbers from the rural districts to the cities, where, however, they eventually tend to die out. As regards this dying-out, so far as the blond long-heads are concerned, Dr. Ammon's figures do not appear to accord with the French conclusions. And having regard to the objections which have been urged against the latter, our author is wise in stating (in the preface) the necessity of further investigations before definite deductions are attempted. He, however, thinks it quite possible that a "selection of long-heads" may be taking place; and expresses the "pious wish" that such may prove to be the case.

As regards the contention of the French investigator that the dark Mediterranean long-heads are the type best adapted for an urban existence, where they choke out the long-headed immigrants, Dr. Ammon[1] considers that this is not supported by the results of his own work; this showing a total absence of the Mediterranean type in three out of the four urban districts, while in the fourth they are considerably less numerous than in the rural districts.

Pursuing the same subject, we find, in the fourteenth chapter of the second part, Dr. Ammon giving a series of interesting details with regard to the differences of skull-proportion and hair-colour between the sons of the immigrants into the towns and those of their native-bred inhabitants. From these it appears that in the smaller towns the sons of town-bred people exceed those of immigrants both in stature, sitting-height, and length of leg, as well as in the leg-index. In large cities, on the other hand, while the first three factors in the former show a similar increase over the country-breds, the leg-index is less. From the country population to the immigrants, from the latter to the sons of immigrants, and from these again to the sons of the city-dwellers there is an increase in the number of long-heads, with a proportionate diminution of round-heads.

In both generations of the town-breds the relative number of blue eyes at first increases and then diminishes in cities of all sizes; in small towns the number of persons with blond hair does the same, while in large towns it remains constant. In the town generation the North European and the Alpine types tend to converge, and the Mediterranean type to disappear. It is in consequence of these changes that a preponderance of blond persons is not observable among the recruits drawn from towns.

Although the above are only a few of the interesting results of the author's investigations, it will be evident that they are of the utmost importance in regard to current French theories as to the general inferiority of the round-heads, and their absorption in cities of the superior long-heads. But, as even the mental superiority of the latter over the former type is by no means admitted by all anthropologists, it is evident that we are at present only on the very threshold of studies of this nature. That results likely to be of real service in connection with the problems presented by urban and rural populations, especially those connected with the present preponderating increase of the former, will ensue from the steady pursuit of such studies, can but be the earnest hope of all those interested (and who is not?) in the future of the higher branches of the human race. R. L.

[1] Page 448. It is a little difficult to reconcile Lapouge's statement as to the dying out of long-heads in cities (see Keane's "Man, Past and Present," p. 520) with his contention that the Mediterranean long-heads show a special suitability for such an existence.

## *LIMNOLOGY.*

*The Microscopy of Drinking-Water.* By G. C. Whipple, Biologist and Director of Mount Prospect Laboratory. Pp. xii + 300, and plates. (Brooklyn, N.Y.: Wiley and Sons. London: Chapman and Hall, Ltd., 1899.)

*Examination of Water (Chemical and Bacteriological).* By W. P. Mason, Professor of Chemistry, Rensselaer Polytechnic. Pp. 135. (New York: Wiley and Sons. London: Chapman and Hall, Ltd., 1899.)

THIS is an example of a class of books in the production of which the Americans are bidding fair to take a lead, the type of book which may be termed the popular practical scientific manual, where the limitation of the subject-matter and the thoroughness of treatment aimed at are worthy of the German, but devoid of that hair-splitting exactness which so often leads to obscurity; while the general style and breadth of treatment are essentially English, and at the same time are saved from the superficiality too common in native technical treatises, by the industry and original ability of the energetic American. At the same time, the present work is not devoid of a certain diffuseness, which we think is referable to the author's enthusiasm leading him into disquisitions too long for the proper purpose of the book, but which is possibly the more marked to us because he is writing about American waters in particular, and about conditions not known in England.

The title may seem to many to claim too much; for Mr. Whipple puts aside at the outset all that relates to bacteria, and takes a very wide view of "drinking-water." He regards the subject of the examination of water as divisible into

(1) Physical examination.
(2) Biological examination.
  (1) Microscopical.
  (2) Bacteriological.
(3) Chemical examination.

A mode of classification which lands him in some inconsistencies—for some Schizomycetes are dealt with later on—and would vitiate the work if it were not clearly set forth that he is concerned solely with that part of the microscopical examination of water which is not bacteriological in the accepted sense of the word, and comes under the head of Limnology, dealing with those organisms which can be filtered out by means of fine-meshed nets or coarse filters incapable of keeping back water-bacteria.

The position reminds us of Miss Kingsley's diatribe against the utility of filters in West Africa.

"A good filter is a very fine thing for clearing drinking water of hippopotami, crocodiles, water snakes, cat-fish, &c. . . . ; but if you think it is going to stop back the microbe of marsh-fever — my good sir, you are mistaken."

Mr. Whipple, however, does not attempt to stop the smaller organisms by his filters, but only deals with the

larger ones, and having laid down his position, he proceeds to show, by his own interesting treatment of the theme, how large and important a subject that of limnology is, and how much neglected it has been in spite of the vast amount of information scattered in detail through the scientific literature of Europe.

Diatoms, Cyanophyceæ, Green Algæ, Fungi, and larger Schizomycetes, Protozoa, Rotifera, Crustacea, Polyzoa, Sponges, and miscellaneous higher aquatic plants and animals are dealt with in detail, and very interesting particulars are given of their numbers, distribution, and seasonal abundance in lakes and rivers, as well as many of their biological peculiarities.

Probably few people are aware that some of these small organisms contain powerfully odorous oils, and are responsible for the strong and unpleasant smell of certain waters, quite apart from decomposition.

We think, in spite of the many interesting facts regarding the existence of thermophilous organisms, the biology of blue-green algæ, &c., the author has missed some opportunities. For instance, we find no discussion or even mention of that puzzling phenomenon, the "Breaking of the Meres," although some of the organisms now known to be concerned—*Anabaena*, *Aphanozomenon*, &c. —are referred to. Again, it seems surprising that no reference occurs to the important *rôle* of such organisms as *Phormidium* in building up "Tufa," "Travertin," and other calcareous and siliceous substrata, particularly as some of the most striking examples occur in the United States.

Prof. Mason's little book proposes, if not protests, too much, as it is manifestly impossible for any author to cover the ground implied in the title in 126 small octavo pages of large print; and although we may give him credit for clear writing, an excellent selection of materials, and a general "up-to-date" style of presentment—including modern tables and charts—we cannot recommend this gossip about the chemical examination of water, with a smattering of bacteriological methods, as a serious text-book for students. On the other hand, we do commend it to the would-be writers of similar books in this country as indicating some of the new directions in which such writings should depart, and so abandon the too well-worn grooves in which our present bacteriologists are creeping onward.

Is not "Wolffhüggle," on p. 107, a misprint for Wolffhügel? It recurs on p. 108.

## HEART AND SCIENCE.

*Kritik der Wissenschaftlichen Erkenntniss.* By Dr. H. v. Schoeler. Pp. viii + 677. (Leipzig: W. Engelmann, 1898.)

A FRIEND of Dr. v. Schoeler's died a victim to his devotion to science, when too late he had reached the conviction that his jealous mistress was not worth the sacrifice he had made for her. What, then, asked v. Schoeler, are the data, what the results of science and philosophy? How shall we free ourselves from their obsession, and make them servants rather than tyrants? Is ethical nihilism the upshot and a pessimism subversive of human endeavour in all directions other than the intellectual? Has Nietzsche, after all, the right of it?

Dr. v. Schoeler answers these questions in the present volume at, perhaps, inordinate length, overloading his work with quotations and instances not always quite relevant to his point. He essays nothing short of a critique of philosophy and of the natural sciences and a constructive theory of life without assumptions. In this task his performance is necessarily very unequal in different sections. His chapter on the ancient philosophy, for instance, is a not very valuable contribution to the history of anticipations. Parmenides is a "Schelling of antiquity," but this does not prevent Heraclitus being called in as a forerunner of the *Identitäts-philosophie*, and the account of Aristotelian science goes little, if at all, beyond what can be learned from G. H. Lewes. On the other hand, where he is more at home and possesses a more living interest, our author's criticisms, if rambling, are often to the point. It is, however, not always quite easy to determine what is intended as mere exegesis, what is the expression of v. Schoeler's own view.

His philosophical sympathies lie on the whole with Kant, interpreted not as containing Idealism of the Hegelian type in germ, but as frankly realistic, relativist, even agnostic. His master is the Kant of the antinomies, and of the unknowable *Ding-an-sich*, treating "freedom" as an ideal amid phenomenal determination. He also has a word of praise for the doctrine of monads, leans a little to Schopenhauer, and accepts the results of evolutionist biology and psychology, though critical of the extent to which they solve ultimate problems, and prepared with Kant to admit the teleological judgment with the limited and relative range allowed it in the third critique. In the scientific field, his interests seem to be mainly what may be termed biological in the wider sense.

The smallness of the results of science in general, however frankly we may admit those results, and the little advance made by either philosophy or science towards the solution of ultimate problems, leads to a provisional relativism almost sceptical. But pure scepticism is negated by the facts of life, and if we reject mechanical constructions as dogmatic, and shrink on our spiritual side from the issue of all dogmatisms and positivisms, and, indeed, of all -isms, in the insanity of Nietzsche, we need to find an escape.

Such an escape, v. Schoeler holds, is not provided by religion. It must be sought for in the idea of humanity, and the furtherance of its ideals in art, in the ethics of family life, and in work in the cause of society. That this earth may or will be dissolved with its phantasmagoria of human knowledge, human passions, human needs, human ideals, lies perhaps not obscurely among the teachings of science. But this pessimism is not subversive of effort and aspiration, so long as it does not despair of the commonwealth. There is no absolute, neither god, nor world, that we can know in other than a relative sense or with other than a relative value, for they have no existence other than a relative one. The advance of the new outlook for the beginning of the twentieth century consists in freeing men from an illusion or a madness, in a new and undogmatic positivism or relativism without pride of intellect, and with a soun hold upon purely relative ideals through the æsthetic and the ethical emotions.

Intellectualism is the curse under which the author's friend fell, a martyr going at the last unwilling to his fate. To this we owe the degeneration held to be typically *fin de siècle*. We must meet the danger, exorcise the curse, by derogating from our claim to construe an absolute, and entering instead upon our heritage as men. "The Ideality of the life of feeling is the remedy."

Dr. v. Schoeler is undoubtedly fitted to write the history of philosophical and scientific ideas in certain fields. His chapter on matter, and his section on the achievement of nineteenth century surgery prove this. And his general power of appreciation and range of interest carry him a long way towards the adequate treatment of his encyclopædic task. But his rhetorical tendencies, shown, for example, in his interesting chapter on Nietzsche, and his exuberance, give the book an ineffectiveness which a smaller work might escape. And there is no index to a critique of all philosophy and all science, though laden on every page with citations !

H. W. B.

## *OUR BOOK SHELF.*

*Les Plantes Utiles du Sénégal—Plantes Indigènes—Plantes Exotiques*. Par Le R. P. A. Sébire. Pp. lxx + 341 (Paris : J. B. Baillière et Fils, 1899.)

RAPID strides have been made of late in opening up to commerce the several European possessions on the West Coast of Africa, and though much has already been done so far as vegetable products are concerned, only a small percentage of such products find their way regularly into European commerce, such, for instance, as palm oil, ground nuts, rubbers, chillies, and a few drugs, including kino, cinchona bark (introduced), strophanthus seeds, kola, &c.

With regard to timbers, there is a wide field for development, as there are many valuable woods in the forests that should find a ready market in Europe. African mahogany, afforded by *Khaya senegalensis* and other trees, is regularly imported into Europe, the trade in this timber having, during the last decade, increased enormously, and though it may lack the figure of Central American mahogany, it commands a ready sale in European ports. Taking into consideration all these facts, any contribution, however small, of the nature of the book under review must be accepted with thanks, so long as the facts and figures are trustworthy. In the preparation of the work the author's aim has been to provide those engaged in agricultural pursuits, or in the development of the vegetable economic resources of Senegal, with a manual of useful instruction. The book affords detailed information on indigenous plants, those that have become acclimatised, and further with those recommended for experimental cultivation.

The first forty pages deal with such subjects as the seasons, water supply, soils, injurious insects, &c., and is followed by a list of exotic economic plants cultivated in the country, with notes on the results obtained, the plants being classified according to their uses. Synoptical tables follow of generic and native names, together with a list of medicinal plants, arranged according to the diseases in the treatment of which they are employed. The main portion of the book, covering 300 pages, consists of a list of plants arranged under their respective natural orders, with scientific and native names and details bearing upon their properties, uses, and distribution. This portion of the work contains much valuable information, and bears evidence of zeal in its preparation. Besides dealing with indigenous and acclimatised plants, notes are given on various exotics and their uses with the view to their introduction into the Colony, or as an aid in determining the properties of indigenous plants upon the assumption that allied species in a given natural order possess similar properties. This is an excellent idea, and adds to the usefulness of the work. An index of Latin and French names, together with lists of native names, complete the work. In a book of this description, written on the spot, one naturally expects to find errors. The scientific names in many instances are obsolete or incorrectly spelled, and due care has not been exercised in the introduction or omission of capital letters, italics, &c. It would have been much better had the information been concentrated under fewer heads, and a good general index of scientific and native names combined would have added to the utility of the book. This may be remedied in another edition, but as the work now stands it can be recommended with confidence to those engaged in the development of the vegetable resources of Tropical Africa as a very useful addition to the limited number of such books already existing. Many illustrations of interesting subjects are intercalated in the text. J. M. HILLIER.

*Applied Geology*. By J. V. Elsden, B.Sc. (Lond.), F.G.S. Part II. Pp. vi + 250, with 186 Figures. (London : "The Quarry" Publishing Co., Ltd., 1899.)

THE first part of this work was noticed in NATURE, vol. lviii. (1898), p. 615. The second part consists of eleven chapters and an appendix. The first chapter (Chapter vi. of the work) deals in 19 pages with unstratified ore deposits. In the following chapter (vii.) the occurrence of the non-metalliferous minerals is described. We have, for example, $2\frac{1}{2}$ pages on coal, $1\frac{1}{2}$ on petroleum, and 1 on diamonds. As these pages include the illustrations, it is clear that the amount of information is completely out of proportion to the importance of the subject. No doubt the author would plead the lack of space for more, but surely in that case he should have made a judicious selection of the literature bearing on the subjects in question, and given full references to it. The same remark as to the almost complete absence of references applies to the book as a whole. Not only would such references have rendered useful short sketches of great subjects, which, standing alone, are almost useless, but they would have given the weight of authority for many statements which, unsupported, appear dogmatic. Chapter viii. is devoted chiefly to prospecting, developing, bed-mining, and vein-mining. The next four chapters deal with "Building and Ornamental Stones." They are chiefly illustrated by sixteen drawings of microscopic rock sections, clearly executed but without any indication of the amount of magnification. On. p. 76 the igneous rocks are classified into three groups—Plutonic, Intrusive and Volcanic ; but it by no means follows, as there stated, that intrusive rocks are microcrystalline, still less that volcanic rocks are necessarily partly or entirely glassy, nor is it logical to classify serpentine as intrusive, while peridotite, of which most serpentines are merely altered examples, is termed plutonic. Rocks used in the arts and manufactures are described in Chapter xiii. Engineering geology, especially the subjects of water-supply, embankments, tunnels and cuttings, occupies Chapters xiv. and xv., and the final chapter is devoted to surface features such as soils. In an appendix are given "simple rough methods for the determination of minerals and rocks," and there is a good index.

The work is very readable, well illustrated, and suited for geological students who wish to learn some of the applications of the science. The practical man will also gain useful hints, though he will feel rather at sea in reading some of the petrographical descriptions, and will wish for more details or references on many practical points.

*On Buds and Stipules.* By the Right Hon. Sir John Lubbock, Bart., M.P., F.R.S., D.C.L., LL.D. With four coloured plates, and 340 figures in the text. Pp. xix + 239. (London: Kegan Paul, Trench, Trübner, and Co., Ltd., 1899.)

THE new volume of the "International Scientific Series" forms a welcome addition to those already published, and it will be read with interest by all who are drawn to a study of the natural history of plants. For although accounts of bud-protection, &c., are to be found scattered through various journals, there existed no connected story of the numberless artifices by which plants shield their winter buds before the appearance of Sir John Lubbock's book. Naturally much of its contents includes matter of common knowledge to those botanists who care for the study of the living plant, but even for them there is much which will be probably found to be novel, and at any rate well worth reading; whilst the freshness and first-hand character of the recorded observations affords a pleasure which those who are acquainted with the author's previous essays in natural history will naturally expect to enjoy from a perusal of the work. It is refreshing to observe that Sir John has not allowed himself to be trammelled too much by orthodoxy—to find that, for example, he declares for the stipular nature of the outgrowths on the petioles of the early leaves of the flowering currant. In the account of the stipules in the genus *Tropaeolum*, however, there seems to be no mention of the interesting fact that the first two leaves (following on the cotyledons) in the common "nasturtium" are stipulate, whereas these structures are absent from the later developed leaves. Indeed, the whole genus seems worth a more extended treatment from the point of view of stipulation, affording, as it does, almost all transitions from complete development to a complete arrest of stipular formation, and these facts are of especial interest in view of the stipulate character of allied forms.

The tendrils of sarsaparilla and also the ligule of grass leaves are considered, and probably with justice (at least as regards the former), as of stipular nature.

The beautiful arrangements by which buds are protected by means of developments of the axillant leaf, as in the plane, maple, *Rhus*, *Kalmia*, &c., are described and well figured; indeed, the excellence of the numerous drawings forms by no means the least welcome feature of the book. Space forbids us to do more than thus briefly indicate a few of the points contained in the volume, which is a most valuable contribution to the literature of a fascinating subject. J. B. F.

*The Philippines and Round About.* By Major G. J. Younghusband. Pp. xiv + 230. (London: Macmillan and Co., Ltd., 1899.)

IN this amusing and well-written book the author gives a very good description of the towns of Iloilo and Manila. The volume is the result of a short visit made soon after the Spanish-American war, of which we get an excellent account. The life and customs of the inhabitants of the Philippines are well described, and the reader cannot fail to be surprised at the slow progress civilisation has made in those parts. This fault is due, without doubt, to the bad condition of the Government. The only outcome of centuries of authority is an absolute want of national discipline. The Filipinos, far from being down-trodden by all the oppression and cruelty they have endured, are lazy and insolent; but, perhaps, this is not altogether surprising seeing that no wholesome authority has been used.

The author has been more interested in incidents of travel than in the natural history of his surroundings. There seems to be little domestic comfort in hotels or houses, and we, who realise so well the value of scientific appliances, cannot fail to be forcibly struck with the descriptions of the primitive state of the sanitary arrangements of the towns.

The book is a valuable addition to works of travel, and will be found a useful guide when visiting the Philippines and their neighbourhood, for good descriptions of life in Java and in the town of Saigon are also given.

*The Slide Valve Simply Explained.* By W. J. Tennant, A.M.I.M.E. (London: Dawbarn and Ward, Ltd.)

THIS little pamphlet of sixty-five pages, forming volume No. 2 of the "Model Engineer Series," was originally intended to help the author's railway students towards the attainment of clear general notions upon the subject of the slide valve. The author conceived the idea of using on a base-board a rotary disc to represent a crank-shaft, together with the idea of obtaining concentric circular diagrams of results, by using a crank-arm marked on the disc as an index-finger, and recording on the base-board the beginnings and ends of the arcs swept out by the crank in the various distribution-periods.

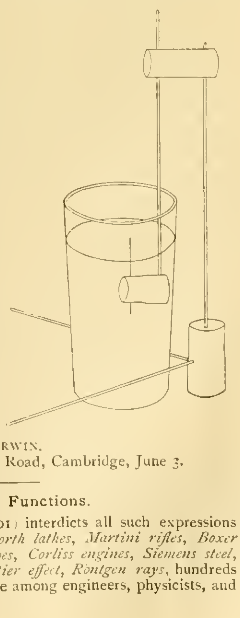
For students with little or no geometrical knowledge the book should be most useful. We think, however, that a student's time would be better employed in acquiring a sufficient amount of geometry to understand the Zeuner diagram, by aid of which the action of the slide valve can be represented more simply, quickly, and conveniently than by the author's disc diagrams. A. S.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### Expansion of Solids by Heat.

THE following simple apparatus for showing the expansion of metals by heat may interest your readers. A cork rests on the table and is kept steady by two horizontal knitting-needles fixed into it. A third knitting-needle fixed in the cork stands in an upright position, and carries a second cork at its top. Another knitting-needle passes through this cork and projects vertically downwards into a glass of water, and carries a third cork at its lower end. This last cork carries a sewing-needle with its point projecting upwards just above the surface of the water. If one of the vertical knitting-needles is heated with a match, the point of the sewing-needle will disappear below the surface of the water; if the other is then heated, the point will appear again. These small movements can be easily seen by watching the reflection of a bright object in the surface of the water.



HORACE DARWIN.

### Bessel Functions.

So Mr. A. B. Basset (p. 101) interdicts all such expressions as *Armstrong guns*, *Whitworth lathes*, *Martini rifles*, *Boxer cartridges*, *Whitehead torpedoes*, *Corliss engines*, *Siemens steel*, *Thomson galvanometers*, *Peltier effect*, *Röntgen rays*, hundreds of which are in common use among engineers, physicists, and

mathematicians, to say nothing of the educated general public! His task is only comparable with the historic one which Mrs. Partington set herself with respect to the Atlantic.

Bangor, June 7. A. Gray.

### Larvæ from the Head of an Antelope.

In preserving the head of an old ♂ Hartebeeste (*A. cokei*), shot on March 31, I took from the nostrils a few hours after death some twenty large larvæ, which I am now forwarding you for identification.

On April 19 I found similar larvæ in the nostrils of an old ♀ Wildebeeste (*C. taurina*); but I think their occurrence in the heads of antelopes in this part of Africa must be comparatively rare; as, though I have shot and preserved the heads of quite a number—including many Hartebeeste—I have not come across them in any other instance. I may add, no appreciable emaciation was shown by the animals from whose heads the larvæ were taken. Richard Crawshay.

Kiu, Uganda Railway, British East Africa, April 29.

These larvæ are those of a fly of the family Oestridæ, and their structure, as well as their habits, shows them to be referable to the genus *Oestrus*, and to be allied to the well-known "Sheep-bot fly," or "Sheep-nostril fly" (*Oestrus ovis*).

Brauer in his "Monographie der Oestriden" (Vienna, 1863) mentions such larvæ as having been found in three species of antelope, and describes two species of fly (*O. variolosus*, Löw., and *O. clarkii*, Shuck.) from South Africa, both probably parasitic on antelopes.

Probably a search through the scattered literature since Brauer wrote would bring to light the record of other species of *Oestrus* with similar habits; but, unless the flies were bred from the larvæ, which would not be very difficult, the species concerned could not be identified.

Walter F. H. Blandford.

48 Wimpole Street, London, June 8.

### Walrus.

Ferdinando Verbesti (1630–1688), in his work in Chinese, "Kwan-yu-wai-ki" (Brit. Mus. copy, 15,297 *a*, 6, fol. 10, *a*), *sub.* "Marine Animals," relates thus: "The *Loh-sze-ma* is about 40 feet long, with short legs, and staying at the bottom of sea comes to the surface very seldom. Its skin is so hard that even swords are unable to pierce it. It has on its forehead horns resembling hooks, with which it hangs itself on a rock, thus sleeping a whole day without slightest awaking." With all deference to Prof. G. Schlegel, who takes the animal here described for the Narwhal (*T'oung Pao*, October 1894, p. 370), I will bolden myself for truth's sake to state that the walrus is meant herein, *Loh-sze-ma* being only a Chinese rendering of *Rosmar*, the Norwegian name of the walrus. The main parts of this description agree well with the description given by Olaus Magnus ("Historia de Gentibus Septentrionalibus," Rome, 1555, p. 757), but not exactly—*e.g.*, the latter author indicates the size of the animal by the words, "maximos ac grandis pisces elephantis magnitudine"; while the former gives it more precisely, though much more exaggerated.[1] Can you or any of your readers oblige me by telling from what very source Verbesti derived his description?

Magnus speaks of the sleeping of the walrus hanging itself on rock with its tusks to be often so sound as to expose its life to danger. Similar story is told in Japan of the sun-fish (*Orthagoriscus mola*), which is said to be floating asleep while its flesh and entrail are being removed (Kaibara, "Yamato Honzô," 1708, book xiii., fol. 43 *b*). Kumagusu Minakata.

### Strawberry Cure for Gout.

In connection with the letter of "F. G." in Nature of June 8 (p. 125), on the strawberry cure of gout, I may mention that last year, when strawberries were so plentiful in England, a lady residing in Kent, who had formerly spent several years in Ceylon, where she had suffered from the wasting and often fatal complaint known as "Ceylon sore mouth" (the chief symptom of which is ulceration of the mucous membrane of the digestive organs), having had a return of the malady, and being unwilling to go abroad to undergo the "grape cure," conceived the happy idea to try strawberries instead, confining her diet to several pounds of these a day with plenty of milk. The remedy was so effectual that after a few weeks she was entirely cured of her malady, and had grown stout and well again.

## THE FRESH-WATER PEARLS OF AMERICA.

The production of pearls by numerous species belonging to the fresh-water bivalve family *Unionidae* has been a matter of common knowledge from time immemorial. Such pearl-bearing mussels occur in the Tay, Isla, and several others of the rivers of the British islands, as well as in many of those of the continent, Mesopotamia, China, and North and South America. As a rule, however, such fresh-water pearls, in Europe at least, are inferior in lustre, and consequently in value, to those obtained from the pearl-oyster; and in those British rivers which produce the pearl-bearing species of *Unio*, it is stated that on the average one pearl is found in every hundred shells, and that only one pearl out of a hundred is fairly clear. During the eighteenth century, however, a considerable number of Irish pearls, ranging in value between 4*l.* and 10*l.*, were obtained, while one specimen, when mounted, realised 80*l.* In Scotland, pearls worth from 3*l.* to 4*l.* each are not unfrequently found, and it is stated that as much as 100*l.* has been paid for an unusually fine example. According to Dr. P. L. Simmonds, between the years 1761 and 1764 ten thousand pounds' worth of Scotch pearls were sent to London, while in the corresponding decade of the present century the amount was considerably more than double that value. During the dry season of 1862, when the lowness of the streams rendered the fishing unusually favourable, more pearls were collected than in any previous year; and the average price consequently fell to fifty shillings, or less. Twenty years ago, when from 5*l.* to 20*l.* was obtained for fine specimens, the general price was, however, much higher; and one Scotch pearl, for which forty guineas was given, is the property of the Queen.

British pearls were well known to the Romans, and it is probable that those from continental rivers were in demand at an equally early date. With the opening-up of the American continent by the Spanish explorers, the world was, however, flooded with a totally new supply of pearls, which there is good reason to believe were also of fresh-water origin. Wonderful are the accounts of the pearls found in the possession of the natives during the De Sota expedition from Florida to the Mississippi in 1540; and three centuries later Messrs. Squier and Davis disinterred vast quantities of damaged pearls from the ancient mounds of Ohio. So great was the number of pearls brought to light by these and other explorers, that it was considered improbable they could have been the products of the fresh-water unios of the country, and they were consequently believed to have been obtained from the pearl-oysters of the Pacific. In later years, however, many naturalists of repute were inclined to doubt the truth of this suggestion; and in an important and interesting memoir on the "Fresh-Water Pearls and Pearl-Fisheries of the United States," recently issued by the U.S. Fishery Commission, the author, Mr. G. F. Kunz, sums up the question as follows: "Notwithstanding the intercourse existing between remote Indian tribes, as shown by many authorities, and the fact that Pacific coast shells have been carried to Arizona, and that clam-shells have been found in Zuñi cities by Lieut. Cushing, it is likely that these pearls came, not from the pearl-oysters of the Pacific coast, but from the marine shells of the Atlantic coast and the fresh-water shells of the eastern part of the continent. It is very probable that the Indians opened the shells to secure the animal as an article of food; that the shells of some

varieties, such as the common clam and conch, were made into wampum; and that the pearls found in the shells were used as ornaments, whether lustreless pearls from the common oyster, or lustrous ones from the *Unio*."

The opinion that these old pearls are of fresh-water origin is based on the fact that many of the North American rivers and lakes still abound with pearl-yielding *Unionidae;* and it is, therefore, the more remarkable that for over two centuries from the date of the Spanish exploration nothing seems to have been ascertained about the latter. As Mr. Kunz says, "the natives have been dispersed, and the white race, occupied with other interests and necessities, took little note of the hosts of fresh-water shells inhabiting the streams and lakes, and did not suspect their power of producing pearls. In the year 1749, John Winthrop, in a natural history catalogue, first mentioned the production of pearls by the fresh-water mussels of the country. But more than a century was destined to elapse before any practical result arose from this knowledge; for it was not till 1857, when the "queen-pearl" was discovered at Notch Brook, near Paterson, New Jersey, that the country awoke to a conception of its hidden treasures. This pearl, which weighed 93 grains, was sold to the Empress Eugénie of France for 500*l*., and is said at the present day to be worth four times that sum.

Its discovery immediately gave rise to an outbreak of "pearl-fever"; and the mussels of Notch Brook and other rivers were gathered by the million and ruthlessly destroyed, frequently with no pecuniary profit. So careless indeed was the mode of operation that a pearl weighing 400 grains, which would probably have proved the record specimen of modern times, was ruined by boiling the mussel in which it was contained. During the first year of the fever, the value of the pearls sent to New York was fully 3000*l*.; in 1858 it fell to about 400*l*., while from 1860–63 the yield was only 300*l*. for the whole period. Although there was some slight revival of the trade in 1868, when pearls were discovered in the Little Miami river, Ohio, it was not till 1876 that any important find was made. But in that year 600*l*. worth were obtained from Waynesville, Ohio, a locality which has since yielded many more pearls, among them one of 38 grains weight, although of somewhat irregular shape. Since 1880 pearls have been found in districts further to the south and west; Kentucky, Tennessee, and Texas becoming the chief pearl-producing States, while Florida has also contributed its quota. New Brunswick and Canada likewise entered into the competition, while in 1889 Wisconsin appeared on the scene with a large consignment of magnificently coloured pearls. Within three months more than 2000*l*. worth of these latter reached New York, including one specimen valued at over 100*l*., the principal colours being purplish-red, copper-red, and deep pink. These finds led to intense activity among the pearl-hunters, with the result that the mussels were nearly exterminated in that district. Other parts of Wisconsin were found, however, to be equally prolific, and since 1889 it is estimated that pearls to the value of at least 5000*l*. have been obtained from that State alone. From exhaustion of the mussel-beds, the pearl excitement in the North-west subsided in the course of a few seasons.

In 1897, the "fever" burst out anew in Arkansas, where it extended west into Indian territory, and north into Missouri, Georgia and certain districts in Tennessee being likewise affected. This period of excitement and activity promised to extend into 1898, of which year no accounts are at present to hand. A remarkable feature about the Arkansas discovery was the fact that a large proportion of the best pearls were obtained lying loose on the mud of the shores, or at the bottom of shallow waters, while sometimes they were found in or upon the soil at some distance from the water. "This peculiar occurrence," writes Mr. Kunz, "is partly explained by the wide extension of the waters in flood times over the low regions of the State, and by the shifting of streams and isolation of 'cut-offs'; but the facts indicate further that under some circumstances, probably by agitation of floods and freshets, the loose pearls are lost or shaken out by the unios. A local impression prevails that the mussels 'shed' them at certain seasons. The fact that the pearls thus found were generally round and well-formed; the aggregation in repeated instances of several or many near or together, and the non-occurrence of shells with them at these places—all point to the washing out of loose pearls from the unios, and their distribution by floods and freshets."

In 1897, the excitement appears to have had somewhat disastrous results in certain districts by abstracting the washers from their regular fields of labour. It has also caused a revival of pearl-hunting in other districts, notably in the neighbourhood of New York. Florida may at present be regarded as an almost unworked country; but, judging from the specimens hitherto obtained, will probably yield a rich harvest. The two largest and finest pearls at present collected from this State weigh respectively 68 and 58 grains, and realised 170*l*. and 120*l*.

Connecticut has also witnessed a revival of pearl-hunting; and here one of the collectors has started the German plan of using a pair of pincers to prise open the valves of the shells.

The mussels that yield pearls in the States all belong to the typical genus *Unio*, and include at least sixteen species. Most pearls appear to be obtained from the common *U. complanatus*, which is a very thick and rounded shell, shaped not unlike a *Cyprina*. Pearls are, however, occasionally found in thin and elongated species, like *U. rectus*. In the Amazon basin of South America, the pearl-bearing species belong to the allied genera *Hyria* and *Castalia*, while in China the profitable species is a *Dipsas*, and is much like the ordinary British *Anodonta* in general form. *Unio* (*Margaritana*) *margaritifera* is the British pearl-mussel.

With regard to the occurrence of the Arkansas pearls on the mud, it may be explained that the *Unionidae* generally dwell in America on clear gravelly bottoms, and that in such situations the pearls when extruded from the shell would be ground up by the pebbles, or would be indistinguishable among them. Not so on the mud of the Arkansas streams, which seems to be the haunt of the unios. Whether the supposition above mentioned, that the pearls are washed out or shed from the shells during life, be well founded, requires further investigation. It is stated that their non-association with shells is due to their having been washed away by floods or freshets after expulsion from the living animal; but this explanation would apply with equal force to the pearls yielded by defunct mussels.

With a view of regulating the industry and preventing, if possible, the reckless destruction of mussels that takes place at each outbreak of the "fever," the U.S. Fish Commission commenced in 1894 an inquiry relating to pearl-fishing in the States; and the result of its labours up to 1898 is embodied in the report quoted above, the general conclusions being summed up as follows:—"The shells are most abundant in swift and clear waters, where the bottom is sandy or gravelly, and the country-rock calcareous. While still numerous in many streams, they have greatly diminished within a few years past, wherever the pearl-hunting enterprise has extended, and at some points are nearly exterminated. The pearls found are few, and those of marketable value represent the destruction of thousands of shells for every pearl obtained. . . . The methods of gathering the shells and extracting the pearls are the simplest and the most primitive, and the activity of a few

seasons generally exhausts the beds. This state of affairs is one that loudly calls for reform. The wealth of unios that fills our rivers and streams is rapidly being destroyed by ignorant and wasteful methods of pearl-hunting; and either some form of protection is important, or, if that be not possible, a wide diffusion of information as to better methods, and particularly the introduction of the tools used in Germany for opening unios far enough to see if there are pearls contained, without destroying the animal, which may then be returned to the water."

In the clearer streams of the country, the best method of collecting the mussels is by wading into the water armed with a water-telescope and a pair of spring nippers affixed to the end of a stick. The water-telescope consists of a long, light, quadrangular tube open above, and shaped to fit the face (to which it is strapped), and closed below with a glass plate. Dressed in waterproof clothing, the pearl-hunter wades along the bed of the stream in a stooping posture, with the lower end of the tube immersed in the water, by which he is enabled to see the mussels on the bottom, and so to pick them out one by one with his nippers. Fresh-water pearls in general are remarkable for their variety of tints, and nowhere is the variation more marked than in those from Wisconsin. Although white is the most common, almost any colour, from pink, purple, or red, to gold, bronze, and black, may be met with; while even a peacock-blue pearl is on record. The golden and wine-coloured specimens are presumably from the beautiful *Unio dromas*, the only common species with a golden or yellow interior to the shell. Pink appears to be the colour most highly esteemed in America, next to which comes red, and then black; but exceptional colours, like sky-blue, command exceptional prices. So far as shape is concerned, the first place is taken by spherical pearls, after which come hemispherical, or bullet-shaped examples, while oval or pear-shaped specimens follow. As regards the maximum prices obtained for American pearls, the statements are somewhat conflicting and indefinite. It seems, however, to be certain that a spherical pink pearl from Tennessee realised 130*l*., while a sky-blue pearl from Caney Fork, in the same State, was sold in America for 190*l*., and subsequently in London for 660*l*. With good luck, there is therefore evidently money to be made by pearl-hunting in the American rivers.

R. L.

## THE GEOLOGY OF MONT BLANC.[1]

MONT BLANC and its aiguilles present some difficult problems to both petrologists and physical geologists; problems, which, though they have something in common, are to a great extent distinct. The authors, however, have grappled with both. Their monograph, as a study of the petrography of the region, is full of valuable information; but we think they have not been quite so successful in dealing with what it is now the fashion to call the tectonics. This portion no doubt contains much that is valuable, but the physical structure of the *massif* of Mont Blanc has been treated too much as if the latter were isolated instead of being, as is really the case, inseparable from the western and central part, perhaps even from the whole, of the Alpine chain.

As most people are aware, the crystalline *massif* of Mont Blanc is defined by two well-marked troughs, occupied by rocks of secondary age, the more northern being furrowed by the valley of Chamonix, the more southern by that of Courmayeur. Each is bounded on the further side from Mont Blanc by crystalline rock, the former by the well-defined range of the Brevent and the Aiguilles Rouges, the latter by one or more varied character, and, generally speaking, of more bedded aspect.

FIG. 1.—Contact of protogine with crystalline schist below the Aiguille du Midi. P, protogine; S, crystalline schists; C, contact.

Of these two marginal crystalline zones, the northern is prolonged to the valley of the Rhone, where it crosses just below Martigny, after which it disappears beneath the sedimentaries of the Western Oberland. The southern passes on to join the Pennine chain to the east of Mont Blanc. The crystalline rock, however, which forms this and the rest of the central *massif*, is more or less fusiform in outline. (The term "amygdaloidal" applied by the authors seems misleading, as its connection with this structure is about equal to that of Monmouth and Macedon.) The central part of the *massif*—though according to them not the very highest rocks of Mont Blanc—consists of a granitoid rock called protogine, formerly said to be composed of quartz, felspar, and talc, and to be the most ancient in the region. The talc is only biotite, more or less hydrous, and the rock intrusive

[1] Recherches Géologiques et Pétrographiques sur le Massif du Mont-Blanc. Par Louis Duparc et Ludovic Mrazec. (Mem. de la Société de Physique et d'Histoire naturelle de Genève.) Tome xxxiii. Ptie 1re.

in the flanking crystallines. Profs. Duparc and Mrazec give an excellent account of the protogine; its microscopic structure and its chemical composition. It is a granite, varying from moderately coarse to slightly porphyritic, the silica percentage occasionally falling rather below that of an average granite. Enclosures of a more basic rock are found in it, which the authors consider, no doubt rightly, to be included fragments of more ancient material and not segregations. The age of this protogine cannot be exactly determined, but in other parts of the Alps a porphyritic granite, occasionally very coarse, yet bearing some resemblance to it, can be seen cutting the truly metamorphic rocks, called by the writer the "upper schists," which apparently are the newest among the Alpine crystallines. The protogine is flanked on each side by a zone of mica schists and fine-grained gneisses, which accordingly must be older than it, and it includes occasional strips of schist. Of these, some may represent wedged-in fragments of the last-named zones, while others probably are dykes, modified by pressure. The affected by subsequent pressure. These are certainly later than the Carboniferous beds, and earlier than the lowest Lias, for they occur as pebbles in a conglomerate of that age. Hence these "porphyries," like similar outbursts in other parts of the Alps, probably represent Permian eruptions. The authors think them not impossibly connected with the vein granites, which would assign the latter also to about the same period.

In discussing the "tectonics," the authors give an excellent *résumé* of the facts, so far as the immediate district of Mont Blanc is concerned, pointing out that the fan structure, of which this mass is generally considered to be a type, is not by any means so simple or so well developed as is generally supposed. They consider the central part of the chain to be a vast synclinal with minor secondary flexures between primitive anticlinals to the north and the south. According to one of them, a section across the range exhibits no less than eight anticlinal bands with intervening synclinals. On this view, we cannot venture to express a definite opinion; we think, however

FIG. 2.—Contact of protogine with crystalline schists below the Aiguille du Midi, seen from the Montagne de la Côte. The schists are at the base of the Aiguille, and of a very dark colour.

whole *massif* is traversed, in some places thickly, with veins of a fine-grained granite, poor in mica (aplite).

The sedimentary rocks associated with the Mont Blanc *massif* belong to two distinct eras. One group occurs but locally; the other has a wide extension, and perhaps was deposited over the whole breadth of this region of the Alps from north to south. The former group belongs to the Carboniferous period. It consists of conglomerates, often coarse, grits, and dark muds (now slates); the latter group forms part of the great Alpine Mesozoic series. At the base, Trias is found; this, however, near the Mont Blanc *massif*, is either feebly represented or absent. It is probably followed everywhere by beds of Rhætic age, but these often cannot be separated from the Lias. In parts of the Alps the series passes gradually upwards into the Eocene; in this district, however, nothing later than some portion of the Jurassic system is preserved. Here and there masses of "porphyry" occur (one with, some without, free quartz), often much that at present a suspense of judgment would be prudent. But that the structure is far less simple than it was formerly represented to be can hardly be doubted. That great complications exist is not surprising, for the region, like the rest of the Alps, has been repeatedly folded. The authors recognise the following as the principal movements: (1) The Caledonian folding, during which the injection of the protogine occurred. This, we presume, so far as it can be dated, would be earlier Palæozoic, perhaps post-Ordovician. Then came the Hercynian folding, which is supposed to have occurred in early Permian times, and to be connected with the ejection of the "porphyries." The axis of this folding ran slightly north of east. During the Mesozoic times, a subsidence continued, the mountains gradually disappearing, while deposition went on steadily.

Then came the Tertiary movements, by which the present chain was formed. We cannot attempt to discuss this part of the subject, for it is a complicated one

and the structure of the chain for a considerable distance to the south and the east must be taken into consideration. That great earth movements had preceded the Carboniferous period, and that mountains of a sort existed during it, and that this period was followed by very acute folding, are certain. We think, however, that the folds in this part of Europe (for reasons which have been published elsewhere) ran approximately from N.N.E. to S.S.W. Evidence of this may indeed be found in the district of which the authors are writing. Such flexures may have been the cause of the frequent trend of outcropping masses along almost the whole of the Alpine chain. During the Triassic period, as has often been observed, highlands, if not mountains, must have existed over more than one large area on the present site of the Alps, which afterwards disappeared beneath a wide-spreading sea. Then came the great Tertiary movements which formed the present chain. The authors apparently treat these as one, but most geologists hold that there were two epochs of maximum disturbance separated by one of comparative rest. The "building" of the present *massif* and the neighbouring mountains should have been treated, we think, in greater detail; for there is more than one interesting problem connected with the courses of the main streams, the positions of watersheds, and the localities chiefly affected by the different movements, which are practically unnoticed. Still the memoir, as a whole, is a very valuable contribution to our knowledge of Alpine geology.

T. G. BONNEY.

## THE BERLIN TUBERCULOSIS CONGRESS (1899).[1]

### II.

(*Section IV. Therapeutics. Section V. Sanatorium Treatment.*)

THE fact that 2000 doctors met together and discussed for two days the treatment, using this term in its broadest sense, of phthisis will, to the observant layman, be of evil omen. When a number of remedies or methods of cure for one disease are all guaranteed by their advocates as being efficacious, the attitude that one at once adopts is one of scepticism. How many doctors would meet together to discuss the treatment of primary syphilis, a disease which can be cured, and how long would it take them to do so if they did? In a multitude of counsellors there may be wisdom, but in a multitude of treatments there is rarely a cure.

The subject-matter of this Section was very fittingly opened by a paper of Dr. Curschmann's (Leipzig) on the curability of phthisis. In the narrow anatomo-histological sense, phthisis is rarely if ever cured; in the clinical sense, however, we can often accurately speak of a cure as having taken place, since the local signs in the lungs not only become arrested, but a certain amount of repair takes place, and the attacked individual becomes practically normal. The majority of cases of cure, however, are relative. In these cases, the local disease, although not coming to an absolute standstill, is of such a nature as to allow of the general condition of the patient remaining good.

The congress listened with great attention to a paper read by Prof. Kobert, of Rostock, on the medical treatment of tuberculosis. The results formulated by the author were of especial value, since they were not confined to his own clinical experience at Görbersdorf, but were derived from a series of inquiries addressed by him to general practitioners and lung specialists throughout Europe—200 in number. These specialists and practitioners had treated during 1898, the year to which the inquiry related, 50,000 cases of tuberculosis. The most interesting of these results are as follows: (1) that we have in our possession no drug which exerts what may be termed a specific action in tuberculosis; (2) that the early stages of phthisis can sometimes be met and cured without medicine of any kind; (3) in acute cases of phthisis, the fatal termination is neither avoided nor appreciably hindered by any kind of medicinal treatment; (4) that in the majority of cases of consumption medicinal treatment along with hygienic treatment is of the greatest possible use in allaying and easing cough, keeping up nutrition, and exerting a controlling action on the tubercle bacillus and its products. Dr. Brieger (Berlin) read a paper upon the treatment of pulmonary tuberculosis by means of tuberculine and allied methods. The author regarded Koch's tuberculine as of distinct value in cases of pure pulmonary tuberculosis, asserting that in several cases an active tuberculous process had by its means been brought to a standstill.

A valuable communication upon the climatic treatment of phthisis was made by Sir Hermann Weber; but since this was reported at length in the *British Medical Journal*, no further mention will be made of it here. A paper of great interest was read by Dr. Dettweiler (Falkenstein), the subject being the hygienic, dietetic and sanatorium treatment of phthisis. Dr. Dettweiler, being the chief physician to one of the largest private sanatoria in Germany, spoke upon this subject out of the fulness of his experience. The author, after emphasising the fact that in phthisis we had to deal, not with a local condition, but a symptom complex, considered in how special a manner a sanatorium could meet the individual requirements of each case, and that by this means alone—viz., meeting every special want or symptom of the patient as it arose—could we hope to be successful in our treatment. It was not from open air, baths, exercise, alcohol, or feeding that we were to expect a "cure," but from the co-operation each day, according to the state of the patient, of all these means. Prof. Winternitz (Vienna) discussed the hydrotherapy of phthisis, and was followed on this subject by Dr. Carl Schütze. Dr. Hölscher (Mülheim) read an interesting paper on the treatment of phthisis by guiacol carbonate and creosotal. The author, after giving a short *résumé* of the results of the continued use of guiacol, emphasised the fact that this method must be used in conjunction with forced feeding, especially in so far as concerns proteids. The guiacol is eliminated in combination with sulphur, and the sulphur thus used can only result from the breaking down of proteid material; hence the importance of the strength of the patient being maintained by a plentiful supply of proteid material in the food. Dr. Cervello (Palermo) described his method of treatment, which consists in the inhalation of a formic aldehyde gaseous compound. Prof. Landerer gave the results he had obtained by the injection of cinamic acid (Zimmtsäure $C_6H_5—CH=CH—CO_2H$). This substance, according to Prof. Landerer, acts by causing an increased leucocytosis, especially in the regions affected by the tubercular process. The action of many other antiseptics in tuberculosis was also considered, including iodoform and glycerine (Dr. R. Hammerschlag) and Izal (Dr. Tunnicliffe), a few preliminary observations with the latter drug tending to show that it acted, as would be expected from its composition, similarly to guiacol and creosote.

The serum treatment of tuberculosis was discussed by Prof. Maragliano (Genoa). This investigator's interesting researches in this field have already attracted considerable attention. The author, after having postulated from his own and Behring's researches the existence of tuberculous antitoxines and their presence in the blood of normal animals and man, stated that the quantity of these could be increased by injection. The injection of such antitoxines rendered animals partially or entirely immune to injections of tuberculous material, and lessened in man the reaction to tuberculine (Koch?). He further

[1] Concluded from p. 109.

affirmed that these "tuberculous antitoxines" had no poisonous action. Prof. Maragliano concluded by considering the harmful influence of pregnancy upon phthisis, and recommended it, when occurring in a phthisical person, to be terminated artificially. Many other interesting papers, for which we cannot find room here, were read in this section.

*Section V.—Sanatorium Treatment.*—Since this tuberculosis congress was the first of its kind, it is difficult, if not incorrect, to speak of any part of it as being a novel feature, but the relative newness of the sanatorium treatment of consumption rendered this Section the most interesting one of the whole congress. As these notes are intended for lay as well as professional readers, perhaps it would not be waste of time and space to discuss what is meant by the sanatorium treatment. It seems to the writer that all that is meant by sanatorium treatment is the placing of patients suffering from phthisis in its different stages in an institution or house where they can be constantly watched by skilled doctors, and where every appliance for rest and exercise and amusement in pure and dry open air, forced feeding ("ubernährung"), and hydrotherapy exist. So much has been said about open-air treatment, Nordrach treatment, and so on, that the more general one's remarks are here the better. If a personal name is to be attached to sanatorium treatment it ought to be that of Brehmer, whose book still remains the classic and, indeed, to all intents and purposes the only book upon the subject. If it is wished to label this treatment with the name of a place, it ought to be called the Görbersdorf treatment, for there in Upper Silesia Brehmer founded his institution, and there it thrives to-day. It must always be remembered that open air is, although an important part, only a part of the whole, insistance upon the food question, and proper and suitable medicines, including alcohol, and above all, the adaptation of all these means to the daily and even hourly fluctuations of the patient, are essential factors in the sanatorium treatment.

The subject matter of the Section was introduced by a paper of Prof. Leyden's, who sketched the development of the sanatorium question. Herr Schmieden (Berlin) read a paper upon the building and arrangement of sanatoria. Dr. Schultzer (Berlin) discussed the arrangement, management and results of sanatorium treatment. The author reckoned the cost of a sanatorium for 120 beds at 3*s.* per diem per patient. He pointed out that the results obtainable from treatment could be greatly improved by the construction of intermediate sanatoria, to which patients almost cured could go and get occupation while being still, to some extent, under treatment. Dr. Edward Kaurin gave an interesting account of the sanatoria for tuberculous patients in Norway. The largest sanatorium is situated on the sea coast, and apparently great attention is paid to diet, for each patient consumes more than two quarts of milk per diem, and about three ounces of butter, in addition to his ordinary meals. The cost per head is 1·20 kronen. Prof. Ewald treated the subject of sanatoria for children. Dr. Rufenacht Walters read a paper on the hygienic dietetic treatment of phthisis in Great Britain. The author emphasised the fact that open-air treatment, combined with increased diet, had long been practised in this country with success. He described shortly the hospitals, convalescent homes, &c., where this treatment had been followed. He pointed out the importance of the modern movement in this country for systematising the struggle against tuberculosis, and concluded with a few pregnant remarks concerning climate in the treatment of tuberculosis, and the necessity for improving the general mode of life of tuberculous patients. Dr. Sinclair Coghill made a communication upon the treatment of phthisis, in which he described the National Hospital for Consumption at Ventnor and the methods practised there.

Many other papers followed in this Section, giving the results at sanatoria situated in the most varied regions, and also discussing the difficulties to be met with and overcome in each country in impressing the hygienic treatment of tuberculosis upon the populace in general. National prejudice and customs, to some extent, perhaps, masked in robust health by the voluntary control of the individual, come very obviously to the surface in disease. The German, disciplined from the cradle to the grave, finds it much less hard to submit to the strict *régime* of the sanatorium than the Englishman, in whose eyes, perhaps, the advantages of individual liberty are somewhat over-estimated.

In these notes, filled with the business of the congress, no space is available even to enumerate its pleasures; suffice it to say that the congressists found ample recreation provided for them by the respective authorities in the evening, and returned refreshed by it to their somewhat depressing subject-matter in the morning.

F. W. TUNNICLIFFE.

## NOTES.

THE award of the sixth De Morgan medal was made by the Council of the London Mathematical Society on Thursday last, June 8. The medallist is Prof. W. Burnside, F.R.S., and the ground of his selection was for his researches in mathematics, particularly in the theory of groups of finite order.

THE death is announced of Dr. L. A. Charpentier, Professor and Fellow of the Faculty of Medicine, Paris, and member of the Academy of Medicine.

THE German Imperial School for the study of tropical diseases, the establishment of which is due to the suggestion of Prof. Koch, is to be settled at Hamburg.

MR. W. MARTINDALE has been elected president of the Pharmacutical Society of Great Britain.

MR. STANDEN, Government Quinologist, Madras, has been deputed to visit Java to study the system of planting cinchona and manufacturing quinine there, and will therefore be absent for some months. It is proposed by the Madras Government to considerably extend the cinchona plantations on the Nilgiris, and a large area has recently been cleared close to the Pykara Falls.

MR. H. J. MACKINDER, reader in geography at the University of Oxford, has just left England in charge of an expedition, the object of which is to make a thorough study of Mount Kenia, in British East Africa.

AS already announced, the autumn meeting of the Iron and Steel Institute will be held at Manchester on August 15–18. The preliminary programme shows that numerous visits to engineering and other industrial establishments have been arranged. Receptions will be given by the Lord Mayor of Manchester and the Mayor of Salford. A detailed programme will be issued when the local arrangements are further advanced. This programme will contain a list of the papers that are expected to be read.

THE Société helvétique des Sciences naturelles will meet at Neuchâtel on July 31–August 2. On the first day, discourses will be delivered by the president, Prof. Maurice de Tribolet, Prof. Roux, Dr. C. E. Guillaume, and Dr. L. Wehrli. On the following day, the various sections will meet, and on August 2 there will be discourses by Prof. Schröter, Dr. Morin, and Prof. R. de Girard. A number of excursions have been arranged, and there is every promise of the meeting being a successful one. The secretary is Prof. Dr. Henri Rivier, Neuchâtel, Vieux-Châtel 11.

WE learn from the Allahabad *Pioneer Mail* that some important changes are being made in the Meteorological Department of the Government of India. These comprise the abolition of a number of observing stations which have not proved worth keeping up, and the substitution for them of others in more favourable localities. Of the latter, most important are stations which are to be established at Cherapunji and one or two other places in Assam, which will enable a more careful watch to be kept over the meteorology of the tea districts, also regarding the periodical rise and fall of the rivers which are so important for the jute trade. Arrangements are also being made, but are not yet concluded, for the establishment of an observatory on Dodabatta Peak, the highest point in the Nilgiris, which is likely to be valuable in connection with the warnings of the monsoon.

THE preliminary programme of the eighteenth congress of the Sanitary Institute, to be held in Southampton, from August 29 to September 2, has now been issued. The president of the congress is Mr. W. H. Preece, K.C.B., F.R.S. Mr. Malcolm Morris will deliver the lecture to the congress, and Bailie J. Dick, chairman of the Health Committee, Glasgow, will deliver the popular lecture. Excursions to places of interest in connection with sanitation will be arranged for those attending the congress. A conversazione will be given by the Mayor (Councillor G. A. E. Hussey). The congress will include three general addresses and lectures. Three sections will meet for two days each, and deal with (1) sanitary science and preventive medicine, presided over by Sir Joseph Ewart; (2) engineering and architecture, presided over by Mr. James Lemon; (3) physics, chemistry and biology, presided over by Prof. Percy F. Frankland, F.R.S. There will also be eight special conferences.

A PARLIAMENTARY paper has just been issued showing the number of experiments performed on living animals during 1898, under licences granted under the Act 39 and 40 Vict., c. 77, distinguishing painless from painful experiments. Nearly all the experiments made under the certificate which dispenses with the obligation to kill the animal before recovering from anæsthesia, have been inoculations made (under anæsthetics upon rodents) with the object of diagnosing rabies. During the past three years, the number of experiments other than those of the nature of inoculations, hypodermic injections or similar proceedings has shown little variation (1516, 1462, 1511), while those of that character have increased (5984, 7360, 7640). Many of these latter experiments are performed in the course of professional duty for the diagnosis of disease, the preparation of antitoxins, the testing of water, and so forth. During the past year 43,000 doses of diphtheria antitoxin have been issued from two institutions.

THE second biennial engineering conference, held at the Institution of Civil Engineers last week, was opened by the president, Mr. W. H. Preece, K.C.B., F.R.S. This conference was not an international one in the sense of that held at Chicago in 1893, or of that which is contemplated in the year 1901 in Glasgow, in connection with the exhibition to be held there, but it may well be Imperial; and in furtherance of this idea the president suggested that, at the next conference, the Council should take measures to secure the presence of some members, delegated specially to represent engineering in parts of the British Empire beyond the seas. In the course of his address, the president remarked: "Science has followed, it has not led engineering. It is their intimate association which is the foundation of all industrial progress. The war of the microbes, the latest development of biology, is a consequence of sanitary requirements. Our knowledge of the diffusion of molecules and the solution of solids has sprung from the investigation into the mechanical properties and constitution of iron and its alloys, and the disturbances of the æther are becoming familiar through the practice of the so-called wireless telegraphy. Facts are derived from accident, observation or practice; laws are the result of research. Engineers have always appreciated science up to the hilt, but they wish that its special votaries were less dogmatic and more modest." Appreciative reference was made to the work of investigators like Newton, Faraday, Lord Kelvin, Lord Armstrong, Lord Lister and Lord Rayleigh; otherwise the remarks quoted would convey the impression that purely scientific investigations, such, for instance, as were made by Faraday, Clerk Maxwell, and Hertz, had followed instead of preceded advances in applied electricity.

THE U.S. Congress has shown appreciation of the valuable work accomplished by the Department of Agriculture by providing increased funds for many of the bureaus and divisions. We learn from the *Experiment Station Record* that the grant recently made by Act of Congress provides an increase of nearly 200,000 dollars over last year, and of more than half a million dollars over the year previous, the total appropriation for the closing fiscal year of the century being 3,726,022 dollars. This includes 720,000 dollars for the agricultural experiment stations in forty-eight States and territories, and a special grant for the establishment and maintenance of experiment stations in Alaska. The largest increases in appropriation are for the Weather Bureau and the Bureau of Animal Industry. The total grant for the Weather Bureau is 1,022,482 dollars, which includes an increase of 60,000 dollars for the maintenance of the new stations in the West Indies and adjacent coast, and 25,000 dollars for the erection of an addition to the present buildings of the Bureau in Washington. The total appropriation for the Bureau of Animal Industry is 1,044,030 dollars. This includes 50,000 dollars additional for investigations and inspection, and 20,000 dollars "for the purchase and equipment of land in the vicinity of Washington for an experiment station for the study of the diseases affecting the domesticated animals." The fund for irrigation investigations has been increased to 35,000 dollars. A grant of 10,000 dollars has been made for tobacco investigations, including the mapping of tobacco soils; study of soils and conditions of growth in Cuba, Sumatra and other competing countries; investigations of the methods of curing, with particular reference to fermentation; and originating improved varieties by means of selection and breeding. The Division of Chemistry receives 34,000 dollars—an increase of 5300 dollars—2500 dollars of which is for the equipment of a new laboratory. These additional grants will materially strengthen the Department of Agriculture and extend its sphere of usefulness.

THE process of manufacturing mechanical wood pulp is described by Mr. W. A. Hare in a volume just received, containing papers read before the Engineering Society of the School of Practical Science, Toronto. Within the past two or three years there has been a marked impetus given to the pulp and paper industry in Canada. Wood pulp will, for many years to come, be used to supply the world's demand for a filler in the manufacture of paper, in many of the coarse grades of which it is the only constituent. It is not confined, however, to the manufacture of paper alone, but is made into many useful articles of daily service, the market for which is increasing rapidly. No country in the world is better adapted than Canada for the establishment and expansion of wood pulp manufactures; and a prosperous future may be anticipated for the industry.

THE report of Mr. W. E. Plummer, Director of the Liverpool Observatory, upon the observations made during 1898, has been issued by the Mersey Docks and Harbour Board.

The results of astronomical and meteorological observations are recorded, and mention is made of the latest addition to the equipment of the observatory—namely, a seismograph, which has been placed in the basement, upon the solid rock which forms the foundation of the observatory. The instrument recorded a disturbance on September 17, 1898, probably having its origin in an earthquake near Tashkent, and it also registered movements produced by an earthquake at Port-au-Prince on December 29. Mr. Plummer hopes that during the year he will be able to trace the effects of tidal motion in the estuaries of the Dee and Mersey upon the seismograph in the observatory.

FROM an intemperate article in the *Journal of Indian Engineering* we learn of a regrettable state of feeling in Hong Kong concerning the comparative efficiencies of the Kowloon Observatory, of which Dr. Doberck is director, and the Jesuit Observatories of Manila and Zi-ka-wei. The Jesuit Fathers have long sent telegraphic messages connected with weather forecasts and storm warnings to the Spanish Consuls in Hong Kong, Shanghai and Singapore, who have forwarded the intelligence to the various newspaper offices in the respective districts, where they have been published for the benefit of the public at large. It is contended on behalf of the Jesuits that this voluntary service was of the greatest assistance to the mercantile marine and commerce of those ports: that the work was well organised and accurate and deserving of support and encouragement. But it is also alleged that the Secretary of War of the United States has peremptorily forbidden the despatch of these meteorological telegrams to any place outside the Philippines, and that this action has been put into operation on an appeal from Dr. Doberck. The charge uttered against Dr. Doberck is that he has used his influence with the U.S. Weather Bureau to move the Secretary of War (now the governing authority in Manila) to suppress the Jesuits' correct telegrams in order that his own forecasts may pass unchallenged. But surely the public can test the accuracy and value of weather forecasts, with or without any assistance from the Manila authorities. It is ill-judged policy to limit the distribution of any scientific information; and as in the present case the work is done voluntarily by the Jesuit Fathers, it is difficult to understand why the issue of the weather despatches has been forbidden.

DURING the last week of May, Mr. Walter Garstang, of the Marine Biological Association, carried out the second of his periodical surveys of the biological and physical conditions of the western region of the English Channel. The steam-tug *Stormcock* was again employed, and the same stations were visited as in February, viz., mid-Channel (50 fathoms), Ushant (60 fathoms), Parsons Bank, 50 miles W.N.W. from Ushant (75 fathoms), and Mounts Bay (45 fathoms). The distribution of temperature presented several noteworthy features. At the Ushant station, in spite of the depth of water, the temperature was found to be uniformly high from top to bottom; but at all other stations a surface layer of warm water overlay a deeper mass of cooler water. This warm surface layer was 7 fathoms deep in Mounts Bay, 10 to 15 fathoms deep in mid-Channel, and 15 to 20 fathoms deep over Parsons Bank. The temperature at 5 fathoms depth was 53°·0 F. in mid-Channel, 53°·2 in Mounts Bay, 54°·1 off Ushant, and 54°·5 at Parsons Bank. Rich collections of plankton were made at all stations in a variety of ways. The apparatus employed consisted of a surface tow-net, a fine vertical net after Hensen's pattern and a pump and 40 fathoms of hose for quantitative work, and a new form of opening and closing net for towing horizontally at any required depth. By means of this net many interesting features in the vertical distribution of plankton at the different stations were brought to light. Among the more interesting forms captured during the cruise may be mentioned the medusa *Hybocodon prolifer* (mid-Channel, and Mounts Bay, 40 fathoms), the siphonophore *Agalmopsis* (Parsons Bank, upper strata), the copepod *Isias clavipes* (Ushant, 3 fathoms), *Tornaria*, the larva of *Balanoglossus* (Parsons Bank, surface), and the eggs and larvæ of the pilchard (Ushant, 60 fathoms, and at the surface at all stations except Mounts Bay).

THE director of the National Observatory of Athens has published (1898) a first large quarto volume of its *Annals*, containing (1) an elaborate discussion of the meteorological observations made from 1839 to 1893, and (2) the detailed observations for the years 1894 and 1895; for the latter year, observations are given for every hour, and means are calculated for daily, ten-daily, monthly and yearly periods. The present observatory was regularly established in 1840, at the expense of Baron Sinas, and he also supplied it with the necessary instruments. The first director was Prof. G. Bouris, and the present director is Prof D. Eginitis. As now constituted, the observatory is divided into three sections: astronomy, meteorology and geodynamics, with a separate chief for each service, under the general superintendence of the director. From this long series of observations we note that the maximum temperature recorded was 105°·3, and the mean of the maxima 100°·2; the minimum was 19°·6, and the mean of the minima 29°·1. The average yearly rainfall (1858–94) was 16 inches; the driest month is July, and the wettest months November and December. The number of rainy days averages 99 in the year. In addition to the statements referring to observations made with instruments during the present century, the author gives, under each section, some interesting quotations relating to the ideas and observations of ancient Greek and Latin writers. Many characteristics of the climate of Greece are contained in almanacs dating from the fifth century B.C., and they are frequently found to confirm the results deduced from modern observations.

WE have received from Prof. H. Mohn, Director of the Norwegian Meteorological Service, a pamphlet on the employment of the boiling point thermometer in determining the pressure of the air and the correction for gravity. As recommended by recent meteorological conferences, the correction for gravity is now generally applied or quoted in meteorological tables. But the correction calculated according to formulæ differs more or less from that determined by actual pendulum experiments, and there are comparatively few meteorological stations where such experiments have been made. It is therefore important for meteorologists to find another means of determining this correction, and in the work in question Prof. Mohn publishes the results of experiments made at a number of land stations; and he shows that the correction for gravity may be very accurately determined by the improved thermometers used in conjunction with a mercurial barometer, the difference of the reduced readings being the correction required. It will be interesting to find whether the methods proposed could be employed at sea; at all events, a comparatively smooth sea would be necessary for the experiments.

AN "Annual Review of Physics," by M. Lucien Poincaré, is a valuable feature of the *Revue générale des Sciences* for May 30. It contains a summary of the chief discoveries made by physicists during the past year, classified under their various headings. Speaking of progress generally, it is pointed out that our knowledge of physics has not been revolutionised by any epoch-making discoveries like those of Röntgen and Zeeman, but that the year has been spent chiefly in extending and completing the knowledge of known phenomena.

THE latest researches on the propagation of malaria, by Prof. Grassi, in conjunction with Bignami and Bastianelli, show that all the species of the genus *Anopheles* hitherto observed by

the writers are capable of transmitting this disease. Experiments bearing on the hereditary transmission of the disease among the mosquitos themselves have hitherto led to negative results. Specimens of *Anopheles claviger* have been bred from parents taken in malarial houses, but no sporozooids have been observed in their salivary glands. Moreover, several observers have allowed themselves to be freely bitten by newly-bred mosquitos taken from malarial districts, but in no case have any ill effects been experienced. The present evidence tends to show that those *Anopheles* which have not bitten malarial patients are not infected, and are incapable of inoculating the disease; a single positive result would, however, disprove this conclusion.

MR. STEWART CULIN still continues his interesting comparative studies of games; and in the *Bulletin* No. 3 of the Free Museum of Science and Art, Philadelphia, 1898, he discusses the "platter" or dice of the American Indians, and finds that they originated from arrows and a throwing-stick used for divinatory purposes. He is of opinion that all the various forms of the game are not only derived, one from another, but that its place of origin may be definitely fixed in the country of the reed arrow and the *atlatl*, or throwing-stick; that is, in the arid region of the South-Western United States and Northern or Central Mexico.

VARIOUS items of Indian folk-lore will be found in the *Journal of the Asiatic Society of Bengal*, vol. lxvii. Çarat Candra Mitra writes on Bengali and Behari bird folk-lore and omen birds. The same author has a paper on coincidences between some Bengali nursery stories and South Indian folk-tales, in which he discusses the migration of folk-tales, and concludes as follows: "The similarity between the Bengali and South Indian versions of these tales can be accounted for only on the supposition that the aboriginal Bengali and Dravidian races assimilated the tales from Aryan settlers, the slight variations between the said two versions being due to the difference between the two borrowing races as regards manners, customs and language." Astronomical folk-lore is ṇarrated by Ramgharib Çhaube.

THE fourteenth fasciculus of the "North American Fauna," under the editorship of Dr. Merriam, is devoted to the biology of the Tres Marias Islands, the larger portion of the text being by Mr. E. W. Nelson. These islands, which lie off the west coast of Mexico, about sixty-five miles from the port of San Blas, have only recently been systematically explored by collectors. As might have been expected, this exploration clearly demonstrates their continental origin, their situation showing that at one period after their separation they formed a single larger island. The birds and mammals seem to have been more susceptible to modifying influences than has been the case with other groups, seven out of ten representatives of the latter, and twelve out of thirty-six of the former, being regarded as entitled to specific or sub-specific distinction.

MR. NELSON has likewise been devoting attention to the squirrels of the mainland of Mexico and Central America, the results of his investigations appearing in the May issue of the *Proc. Washington Academy*. It is concluded that the arboreal squirrels of North America should be divided, from the characters of the skull, aided sometimes by external peculiarities, into ten distinct sub-generic groups, four of which receive new names. The sub-genera are stated to occupy clearly defined geographical areas—a fact which speaks clearly as to their intrinsic importance; and it is further noticeable that the ranges of the most closely allied groups are invariably separated from one another by distinct gaps. Considerable importance as a group-character is attached to the presence or absence of the anterior upper premolar, and its relative size when developed.

IN his paper on "Mid-winter Surface and Deep Tow-nettings in the Irish Sea," recently published in the *Trans. Liverpool Biol. Soc.*, Mr. I. C. Thompson urges the importance of correlating the gatherings taken from upper and lower strata at the same time, much remaining to be learnt as to the effects of temperature and other influences upon the minute forms of marine life.

IN the *Bol. Mus. Paraense* for December last, the energetic director of the museum, Dr. E. Goeldi, laments the unsatisfactory state of our knowledge of the Brazilian fish-fauna, mentioning at the same time that although it is a subject to which his attention has long been directed, means and opportunity have been lacking. A commencement is, however, now made in the present synopsis of the fishes of Amazonia and the Guianas, which includes nearly forty pages of text, and a double coloured plate. The excellent execution of two of the figures in the latter, representing species recently described by Mr. Boulenger, is a very satisfactory feature.

THE April number of the *Agricultural Gazette of New South Wales* contains an illustrated account of a small ostrich-farm at South Head, where nine birds are kept. The methods of plucking and making-up the feathers are described and photographed. The annual product of each bird is worth from 10*l.* to 15*l.*; and the owner is of opinion that the industry is likely to prove a thriving one in the Colony. He considers that the birds, instead of being allowed to roam over large areas, as at the Cape, should be kept in small paddocks, and shifted from one to another of these at short intervals.

A PAPER by Mr. F. A. Lucas on the fossil bison of North America, published in the *Proc. U.S. Mus.*, vol. xxi., pp. 755-777, is specially noticeable for its wealth of illustration, having over twenty plates. The author, in opposition to some previous writers, is of opinion that all the bison skulls hitherto found in America are specifically distinct from the *Bos priscus* of Europe. No less than six extinct species are recognised; and while one of these is certainly a very distinct form, yet if all the others are valid species, it may be taken as certain that the fossil bison skulls of Europe would also permit of considerable specific division. One of the most important items in the paper is the determination that the so-called *Bos scaphoceras* of Cope, from Nicaragua, is not a bison at all, but a sheep. It seemed very strange that a representative of the former animals should have wandered so far south during the Pleistocene.

PERHAPS the most generally interesting article in the May number of the *American Naturalist* is one by Mr. Herrick, describing a case of the occurrence of a small hen's egg within one of ordinary size. Not that such abnormalities are uncommon—far from it. But the interest of the present case lies in the fact that the enclosed egg was situated in the yolk, instead of in the albumen of the larger specimen. In this respect it appears to be unique. The different types of such abnormalities are considered in detail. In ordinary cases, it seems that the small included egg represents a fragment of a normal ovum which has been ruptured, and has thus parted with some of its substance after leaving the ovary. Usually this fragment is treated in the oviduct like a full-sized egg and duly laid; but it may rarely be driven by antiperistaltic action up the tube so as to collide with the mother-egg, with which it fuses. From the general absence of yolks in such included small eggs, the ruptures that take place in the upper part of the oviduct must, as a rule, be confined to the albumen. Other explanations are given to account for double- or treble-yolked eggs.

IT is curious to note how the natural history of the fast-waning group of giant land tortoises is being gradually pieced

together from the evidences of living specimens transported far from their original habitat. An instance of this is afforded by Mr. E. R. Waite's description in the last issue of the *Records of the Australian Museum* of a male and female of *Testudo nigrita* recently living in the grounds of the Gladesville Hospital, near Sydney. The female, which died in 1896, was brought from the Galapagos in 1853, and the male, which has been acquired by Mr. Walter Rothschild, about 1866. Unfortunately, in neither case is there any evidence as to the particular island in the Galapagos group from which they were obtained, so that the exact habitat of the species still remains unknown.

SPECIAL interest is naturally felt at the present time in the geology of many of the islands in the Malay Archipelago, and therefore the summary just published by Dr. B. Kotô, Professor of Geology at Tōkyō, will be of service (*Journ. College of Science*, Imp. Univ. of Tōkyō, Japan, vol. xi. part 2). The author acknowledges his indebtedness to the labours of Prof. Suess; but he gives additional information, his object being to compare the structure and physical features of Taiwan with those of the Far Eastern Indies. Brief references are made to a great variety of strata and to the volcanic phenomena.

WE have received the summary report of the Geological Survey of Canada for 1898, in which the Director, Dr. G. M. Dawson, records the progress of the Survey, and quotes from the reports of the several officers on the staff "the more important results of their investigations, particularly such as may be of immediate value to the public from an economic standpoint." In northern Alberta some further experimental borings have been made in search of petroleum, and great trouble has been experienced in the effort to penetrate the "tar-sands" at the base of the Cretaceous strata, owing to "the clotting of the casing and tools with the heavy tarry petroleum, or maltha, mixed with sand, which was thrown up by the discharge of gas." The indications of oil-bearing strata have been proved over a large area, and it is hoped that the liquid petroleum may be found in the Devonian limestones which underlie the Cretaceous rocks.

MR. R. G. MCCONNELL and Mr. J. B. Tyrrell's report on the Klondike Region, Yukon District, is referred to in the publication mentioned in the foregoing note. The productive part of the Klondike gold-field, as at present known, covers an area of one thousand square miles. The gold occurs in the gravels flooring the bottom of the valleys, in stream-terraces lining the lower slopes of the valleys, and in a remarkable moraine or glacial deposit that occurs along the slopes of Eldorado and Bonanza creeks. The gold has been derived from the rocks of the immediate vicinity, and these consist of schists probably of Cambrian age. In various regions the want of good topographical surveys is a sad hindrance to the geological work, but that this is carried on in various portions of the vast territory of Canada with great energy and enthusiasm is evident from the details enumerated in this report of the Canadian Geological Survey. There are numerous observations on petrology, palæontology, and natural history generally. A large number of reptilian remains have been obtained from the Belly River formation in the Red Deer River district. The age of the formation, judged by the invertebrate fauna, is considered by Mr. Whiteaves to be the same as that of the Laramie (Cretaceous) series.

IN NATURE for January 19 we gave a brief account of the progress of the Maryland Geological Survey, which is under the direction of Prof. W. B. Clark, State Geologist. We have since received the second volume issued by the Survey, which embodies the full reports to which we previously alluded. As in the case of the first volume, it is beautifully printed and handsomely illustrated. The coloured plates picturing the macroscopic appearance of various granites and the Potomac marble are particularly good. There are, moreover, numerous pictorial views of quarries and of the physical features; there are excellent topographic and geological maps, and reproductions of some of the earlier topographic maps dating from 1527. The volume is mainly occupied (1) with an account of the building and decorative stones of Maryland, by Mr. G. P. Merrill and Mr. E. B. Mathews, by whom the physical, chemical, and economic properties of the stones, and their distribution, are very fully considered; and (2) by a report on the cartography of Maryland by Mr. H. Gannett and Mr. E. B. Mathews, who deal with the aims and objects of cartography, and with the maps and map-makers of Maryland.

MR. G. K. GILBERT describes a "Bowlder-Pavement" (to use the American spelling) at Wilson village, about twelve miles east of Niagara river, New York (*Journal of Geology*, Nov.-Dec. 1898). Such a pavement is formed when the boulders in till or boulder-clay are grouped in an approximately horizontal plane, and are striated on their upper surfaces in a common direction. The features are indicative of local glacial action which has affected a previously accumulated till, this action having removed a certain amount of material and caused the pressing down and striation of boulders along the plane of erosion.

IN treating of the glacial sculpture in Western New York (*Bull. Geol. Soc. America*, March), Mr. Gilbert shows how the broad plateau of Niagara limestone was but little modified, while its escarpment was rendered more prominent owing to the excavation by ice of the underlying shales which occupy the lowlands. Mr. Gilbert draws attention to a flexure produced by ice-action in the Medina shales at Thirty-mile Point, New York; and in a subsequent article he describes some giant ripple-marks in the Medina sandstones of New York, and these suggest that the formation was laid down in a large ocean whose waters were agitated by storm waves sixty feet high.

MR. G. CLARKE NUTTALL contributes to the current number of *The Contemporary Review* a popular account of the dependence of the flavour of tobacco upon the activity of bacteria during that important stage in the preparation of tobacco known as fermentation. Interesting reference is made to the work of Suchsland, who examined the germs which he found in the fermenting heaps of the finest West Indian tobacco. This German bacteriologist isolated and cultivated these bacteria, and then introduced some into quantities of inferior German tobacco, which was subsequently transformed so that connoisseurs could not distinguish it from the finest brands of tobacco.

WE have received from Messrs. Dulau and Co. a copious list of books and papers in British botany offered for sale.

COURSES of instruction in cryptogamic and cytological botany are given at the Marine Biological Laboratory, Woods Hole, Mass., during July and the early part of August.

HERR J. DORFLER, the compiler of the *Botanists' Directory*, proposes to publish a new edition about the commencement of the year 1900, and desires the co-operation of the botanists of all countries. His address is Barichgasse 36, Vienna IV.

A CIRCULAR has been issued inviting the attention of biologists to the biological station at Ambleteuse, in the Department of Pas-de-Calais, France. It has been erected very much on the plan of the American station at Wood's Hole, and is primarily designed as a summer school for biological students in connection with the Catholic University of Lille.

THE Reading College Agricultural Department has just issued its Fifth Annual Report on Field Experiments for 1898. The experiments were carried on with the co-operation of the Coun

Councils of Berkshire, Oxfordshire, Dorsetshire, and Hampshire, subsidies being granted by these bodies to the College to meet the expenses. The experiments were chiefly concerned with manuring and the rotation of crops, and furnished results which ought to be useful to farmers. Only one disease of cultivated crops, the "finger-and-toe," appears to have been attacked. Experiments on the cultivation of the sugar-beet in the neighbourhood of Reading gave good results. We notice that the staff of the College engaged on the field experimental work comprised two lecturers in agriculture, a lecturer in chemistry, an assistant chemist, a lecturer in geology and meteorology, and the director of the agricultural department, but no botanist or entomologist.

Many admirers of Tyndall's writings will be pleased to know that the volume entitled "Hours of Exercise in the Alps," which has been out of print for some years—the last edition (the third) having appeared so far back as 1873—has been reprinted. Many adventures in the Alps and elsewhere are narrated therein, and the volume has as much freshness and vigour now as ever it had. Messrs. Longmans, Green, and Co. are the publishers.

A new volume of the "Year-Book of the Scientific and Learned Societies of Great Britain and Ireland" has just been published by Messrs. Charles Griffin and Co. The volume contains, not only particulars as to officers, meetings, and membership of learned societies, but also lists of papers read before, or published by, every Society of importance throughout the kingdom during 1898. As a convenient work of reference, the volume only needs to be known to be used.

The current number of the *Photogram* contains as a supplement a very excellent reproduction of a snow scene, entitled "A Winter's Night," on special rough velox paper. The same number also contains the spectrum of iron and the solar comparison (on a slightly reduced scale), which has recently been obtained direct on a film thirty inches long at one exposure at the Solar Physics Observatory, South Kensington.

As Rugby was the first of the Public Schools to afford facilities for the study of science, we look to the Natural History Society of the School for a good report; and the one just issued is not disappointing. A prize essay, by Mr. P. H. Bahr, on "The Birds of Staffordshire and North Wales," is included in the report, together with reports on the work of various sections, and Mr. G. M. Seabroke's report on the observations made at the Temple Observatory in 1898.

The course of study in technical electricity, arranged by M. Eric Gerard for the Montefiore Electro-technical Institute of the University of Liége, formed the basis of a volume of "Leçons sur l'Electricité" written by M. Gerard, and published several years ago by MM. Gauthier Villars et Fils. The first volume of the sixth edition of this work has just been received. The subjects dealt with are the theory of electricity and magnetism, electro-magnetic induction, electrical measurements, thermo-electricity, dynamo-electric machines, transformers and alternating currents. Many changes have necessarily been made in order to include some of the more important inventions and discoveries of the past few years. The volume now runs into 819 pp., and is illustrated with 388 figures.

Many practical hints for photographers are given by Dr. E. Vogel in his "Taschenbuch der praktischen Photographie," the sixth revised and enlarged edition of which has just been published by the firm of Gustav Schmidt, Berlin. Among the additions to the volume is a description of the preparation of, and printing with, potassium bichromate paper (Gummidruck). Concise notes on the materials and methods available for the production of good negatives and various kinds of prints form a characteristic of this photographer's pocket-book.—Another photographic publication just published by the firm of Gustav Schmidt is a new part of the fourth edition of the late Dr. H. W. Vogel's "Handbuch der Photographie," edited by P. Hanneke. The subject of the new section is photographic printing by different kinds of processes.

"Picture Taking and Picturing Making" is the title of a neat and clearly printed little book of 115 pages, published by the Eastman Kodak Company. The object of this guide, as we may call it, is not to deluge the reader with theories and technicalities of photographic optics and formulæ, but to state clearly the main features regarding the production of good negatives, prints, and lantern slides. Parts of the book are somewhat familiar, in that they have appeared in the small Kodak manual; but the reader will find much that is new and useful. Needless to say, there are numerous and well-reproduced illustrations.

In the "Year-Book of Photography and Amateurs' Guide" the reader will find that the 650 pages of which it is composed contain a mine of information that should be of the greatest service to the photographer, whether he be amateur or professional. The five sections of the book, which bring before us progress and practice, being a collection of helpful articles by practical photographers, the tourists' companion and holiday guide from the photographic point of view, winter work, facts and formulæ, and, lastly, novelties of the year, contain useful and valuable information suitable for every one. Not less important is the collection of fine reproductions from negatives, on many different subjects, taken with several kinds of cameras and shutters, which lends an additional charm to this year's volume. The author has succeeded in presenting his readers with, not only an interesting volume to read, but one that should be at the side of every amateur for reference.

A second edition of "The Aborigines of Tasmania," by Mr. H. Ling Roth, has been published by Messrs. F. King and Sons, Halifax. In a supplementary note to the preface, Prof. E. B. Tylor points out that since the publication of the first edition, nine years ago, noteworthy progress has been made in the anthropological study of the Tasmanians. He adds, "That these rude savages remained within the present century representatives of the immensely ancient Palæolithic period, has become an admitted fact. . . . That the workmanship of the Tasmanians may be generally taken as below that of the Palæolithic Drift and Cave men, is apparent from the absence of any Tasmanian implement comparable to the symmetrical pointed picks worked on both sides, characteristic of the Mammoth Period in Europe." The additional information and figures referring to the position of the Tasmanians in the history of the human race make Mr. Ling Roth's volume of exceptional interest to students of anthropology.

The additions to the Zoological Society's Gardens during the past week include a Sooty Mangabey (*Cercocebus fuliginosus*, ♀) from West Africa, presented by Mr. G. Le Tantt; a Bonnet Monkey (*Macacus sinicus*, ♀) from India, presented by Mrs. C. Tarrant; two Slender Loris (*Loris gracilis*) from Ceylon, presented by Mr. Stanley S. Flower; a Leopard (*Felis pardus*, ♂) from Ceylon, presented by Mr. Edward Booth; a Black-backed Jackal (*Canis mesomelas*) from South Africa, presented by Mr. David D. Keith; a Two-spotted Paradoxure (*Nandinia binotata*) from West Africa, presented by Mr. Arthur Knights; a Vervet Monkey (*Cercopithecus lalandii*) from South Africa, presented by Mr. G. Marson; a Brown Gannet (*Sula leucogastra*) from Accra, presented by Miss Williams; a White-backed Piping Crow (*Gymnorhina leuconota*) from Australia, presented by Mr. G. T. Harris; two Common Vipers (*Vipera berus*) from Hampshire, presented by Mr. Chas.

C. Dallas; an Algerian Skink (*Eumeces algeriensis*) from North Africa, presented by Mr. R. H. Archer; a Rufescent Snake (*Leptodira hotambaeia*), a Hissing Sand Snake (*Psammophis sibilans*) from South Africa, presented by Mr. W. Champion; three Barbary Turtle Doves (*Turtur risorius*) from Africa, presented by Colonel E. J. Gardiner; three Blue-necked Cassowaries (*Casuarius intensus*) from New Guinea, a Senegal Parrot (*Paeocephalus senegalensis*) from West Africa, two Mute Swans (*Cygnus olor*, 2 ♂), European; an Echidna (*Echidna hystrix*) from New South Wales, deposited; a Hunting Crow (*Cissa venatoria*) from India, three Bar-tailed Godwits (*Limosa lapponica*), four Black-tailed Godwits (*Limosa aegocephala*), ten Green Lizards (*Lacerta viridis*), four Toads (*Bombinator bombinus*), European, purchased; a Japanese Deer (*Cervus sika*, ♂), an English Wild Cow (*Bos taurus*), two Squirrel-like Phalangers (*Petaurus sciureus*, 2 ♀), two Short-headed Phalangers (*Petaurus breviceps*, 2 ♂), a Patagonian Cavy (*Dolichotus patachonica*), a Crested Porcupine (*Hystrix cristata*), a Hybrid Lemur (between *Lemur macaco* and *Lemur brunneus*), born in the Gardens.

## OUR ASTRONOMICAL COLUMN.

Tempel's Comet (1873 II.)—Continued from *Astr. Nach.* (Bd. 149, No. 3554).

*Ephemeris for 12h. Paris Mean Time.*

| 1899. | R.A. h. m. s. | Decl. ° ′ ″ | Br. |
|---|---|---|---|
| June 15 | 19 54 47·2 | 5 12 25 | |
| 16 | 56 11·5 | 5 22 24 | |
| 17 | 57 35·4 | 5 33 2 | 1·829 |
| 18 | 19 58 58·9 | 5 44 20 | |
| 19 | 20 0 21·9 | 5 56 19 | |
| 20 | 1 44·5 | 6 8 59 | |
| 21 | 3 6·7 | 6 22 21 | 2·048 |
| 22 | 4 28·5 | 6 36 27 | |
| 23 | 5 49·8 | 6 51 16 | |
| 24 | 7 10·7 | 7 6 49 | |
| 25 | 20 8 31·1 | 7 23 7 | 2·281 |

The comet is now more than four times as bright as when it was first re-observed by Prof. Perrine at Lick on May 6. Perihelion passage occurs on the 18th inst. During the period included in the above ephemeris the comet travels from the south-eastern part of Aquila to the north-west of Capricornus, being about 5° due north of $\alpha$ Capricorni on the 25th.

Return of Comet Holmes (1892 III.).—Continued from *Astr. Nach.* (Bd. 149, No. 3553).

*Ephemeris for 12h. Greenwich Mean Time.*

| 1899. | R.A. h. m. s. | Decl. ° ′ ″ | Br. |
|---|---|---|---|
| June 15 | 1 22 38·3 | + 18 47 18 | 0·0341 |
| 17 | 22 56·5 | 19 23 22 | |
| 19 | 29 13·8 | 19 59 19 | |
| 21 | 32 29·9 | 20 35 8 | 0·0351 |
| 23 | 35 44·9 | 21 10 50 | |
| 25 | 38 58·8 | 21 46 25 | |
| 27 | 42 11·4 | 22 21 51 | 0·0362 |
| 29 | 1 45 22·7 | + 22 57 10 | |

During the above period the comet moves from near $\eta$ Piscium to about 2 degrees north of $\beta$ Arietis.

A telegram from Kiel, dated June 12, announces the first detection of this comet by Prof. Perrine at the Lick Observatory. The observation was made on June 10, at 15h. 2·2m. Lick Mean Time, the recorded position being

R.A. = 1h. 15m. 32s.
Decl. = + 17° 29′ 39″,

which will be seen to be fairly in agreement with the computed position. The comet is described as being very faint.

Comet 1899 *a* (Swift).—A circular from the Central Bureau at Kiel calls attention to the importance of the increase of brightness of this comet, which was recorded by several observers on June 4 last. Herr Kreutz has received a telegram from Herr Pokrowsky, of Dorpat, stating that communications received by him from Vienna, Bamburg and Hamburg, confirm the fact that on June 4 a decided brightening of this comet took place. The increase of magnitude was from 6 on June 2nd and 3rd to $5\frac{1}{3}$ on the 4th. A telegram also from Herr Hartwig gives further details. "The nucleus was of 9·5 magnitude, the total brightness being of magnitude 5. Greatest diameter of Coma about 9′; increase of brightness undoubted."

Another, from Herr Schorr, states: "Strong eccentric fixed star-like nucleus of 6·5 magnitude. Total brightness of comet 5 magnitude. Coma 9′ in diameter."

It will also be remembered that there was a decided increase in brightness of this comet from May 9 to 23, after which it gradually began to decline until the above sudden change was noted.

White Spot on Jupiter.—Herr Ph. Fauth, writing from a private observatory at Landstuhl to *Astr. Nach.* (Bd. 149, No. 3570), announces the observation on several occasions of a brilliant white spot on the north-eastern belt of the planet. The marking was observed to pass central meridian on May 8 at 11h. 25m., and on May 18 at 9h. 33m. It is about 4″ in diameter. The observations were made with a telescope of 7 inches aperture.

Two New Variable Stars.—M. Luizet, of the Lyons Observatory, announces in *Astr. Nach.* (Bd. 149, No. 3570) his observations leading to the discovery of two new variable stars in the constellations Vulpecula and Cygnus respectively.

The first is U Vulpeculae,

B.D. + 20°·4200. R.A. = 19h. 30m. 17·3s. } 1855·0.
Decl. = + 20° 0′·8. }

Four comparison stars were used and forty-three observations made during the period August 4 to December 26, 1898. These observations after reduction are plotted as the light curve, which is symmetrical and similar to that of $\zeta$ Geminorum. A maximum was found to fall on the date

1898 October, 21·61 Paris Mean Time,

and this in conjunction with a previously observed maximum by MM. Müller and Kempf,

1897 October, 2·4765 Paris Mean Time,

gives the period as

8·003 days.

The elements of the star U Vulpeculæ are therefore adopted as

1897 October, 2·4765 Paris M.T. + 8·003d. E.

The second variable is S U Cygni, the position being

B.D. + 28°·3460. R.A. = 19h. 39m. 1 0s. } 1855·0.
Decl. = + 28° 54′·9. }

Fifty-eight observations of this star were made from July 9 to December 26, 1898, and the results again plotted to give the light curve.

The period is determined to be

3·846d.,

and succeeding maxima may be calculated from the elements:

1897 October, 4·6665 Paris M.T. + 3·846d. E.

This star has a light curve showing an *irregular* decrease of brightness from maximum during about 2·7d., and a more regular increase during 1·1d., these features showing the variability to be somewhat analogous to that of $\delta$ Cephei.

## THE BORE AT MONCTON, BAY OF FUNDY.[1]

Moncton is situated on the Petitcodiac River, nineteen miles above the mouth of the Petitcodiac, where it enters the Bay of Fundy. This part of the river is more correctly an estuary which continues thirteen miles further up, as far as Salisbury Junction. At high tide the river at Moncton forms a sheet of water half a mile in width, while at low tide it consists of mud banks and flats, with a stream about 500 feet wide

[1] Abridged by Prof. G. H. Darwin from an advance copy of the Report for 1898 of the Tidal Department of the Survey of Canada, sent by Mr. W. Bell Dawson.

running with a strong current in a devious channel amongst the bars and mud flats, which are left dry at low water.

The run of the rising tide first breaks into a bore at Stony Creek, eight miles below Moncton, and it continues to the head of the estuary at Salisbury, thirteen miles above. The total distance on the river that a bore occurs is therefore twenty-one miles.

With regard to the time of arrival of the bore at Moncton, this really corresponds with the time of half tide. At the central moment between the previous and the following high water, which we may term the theoretical time of low water, the level of the water in the river is still falling; and it continues to fall, though at a much slower rate, for about three hours longer before the bore arrives. The time of the arrival of the bore is thus only about three hours before the next high water, which serves to account for the very rapid rise which takes place after the bore passes.

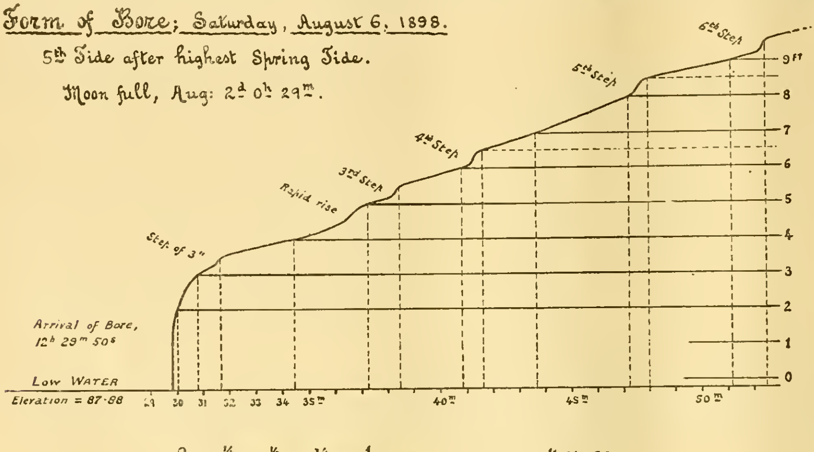
The rate at which the tide falls amounts at its maximum to eight feet per hour; but after the theoretical time of low water, the rate of fall soon becomes very slow, and the river appears to a casual observer to remain at the same level for some two hours before the arrival of the bore. The flow, however, continues to be fairly swift; and it no doubt still consists of tide water. The rate of fall in the level of the water, as measured shortly after spring tides, was found to be as follows:—

From $4\frac{1}{2}$ to $2\frac{1}{4}$ hours before arrival of bore, rate of fall *six inches* per hour.
,, $2\frac{1}{4}$ to 1 hour ,, ,, ,, ,, *four inches* ,,
,, 40m. to 15m. ,, ,, ,, ,, *three inches* ,,

The first observation of the bore was made on the evening of August 4. The point of view commanded some two or three miles down stream below the bend, as well as the foreshore opposite Moncton. The moon was a little past the full, and was well risen before the bore arrived; and the sky was then clear also. There was a very slight breeze, and in the stillness sounds could be distinctly heard. It was thus at the spring tides, and twenty-four hours after the lowest of the tides at that moon.

The first sound of the approaching bore was heard at 23h. 8m., in 60th meridian time, and two minutes later the sound was quite distinct. This sound was very similar to the noise of a distant train when heard across water. It afterwards increased to the usual hissing and rushing sound of broken water, as in a rapid on a river; but there was no mingling in this sound of any roar, such as a waterfall makes when falling into deep water, even from a moderate height. The bore arrived at the wharf at 23h. 19m., or eleven minutes after its sound was first heard. The rapidly-flowing layer of incoming tide advanced over the current of the river in the opposite direction, with a front of broken and foaming water, which had a height of perhaps two or three feet. The front edge was by no means straight. The higher part of the bore extended across the waterway, and this was bent back and also heightened in the middle by the opposing current of the river, which is naturally swiftest at the centre of the stream. Beyond this the bore formed a long sweep, where it broke over the flats, retarded and decreasing in height towards the further bank of the river.

The surface current of the water following the main front has the same speed of flow as its rate of advance; and after the main front passes, there usually follow a series of others, stepped up a few inches of additional height. These form irregular lines of curve across the surface of the advancing tide, which do not extend far without interruption. These may be due in part to back-wash from the flats into the main channel. As seen in the day-time, the water forming the bore is excessively muddy and reddish-yellow in colour, just as the outflowing water of the river also is. The actual broken water in the front is nearly white, except at the shore end; but the long edge of the advancing water on the flats appears nearly black in strong sunlight. With a stiff breeze down stream, the sound of the bore cannot be heard till it has approached within a few hundred yards.



CORRESPONDING SCALE OF DISTANCE FROM AVERAGE SPEED OF BORE.

AVERAGE SPEED AS OBSERVED = 8·47 MILES PER HOUR.

During the neap tides the bore still appears, and the front edge usually breaks a few inches high. But there are times when it consists merely of a heavy ripple, like the side waves from the bow of a steamer when they are advancing over still water; and it then only breaks occasionally, except in passing over the flats.

The rate of advance of the bore was timed from a point of observation on one of the upper wharves, which commands a view around the bend of the river. The velocity, as determined from several observations, was about $8\frac{1}{2}$ miles an hour.

To ascertain the form of the bore, and its rate of rise, a graduated board 13 feet high was set up in the front of the wharf, at which the tide gauge was placed. The current, after the bore passes, appears to have the same surface velocity as the rate of advance of the bore itself.

The height of the bore, as observed at spring and neap tides, and the rise of the water following it, are shown in the report by diagrams, of which one is reproduced here. The rise is by

no means uniform. There are at times distinct steps, which are sometimes visible as such, on the surface of the incoming water. At other times the water holds its level for a short interval, and then rises rapidly afterwards to make up, as it were, for lost time.

The diagram may also be taken to represent the form of the bore, or its profile along the river at any given moment. Strictly speaking, this involves the assumption that the whole mass of water moves forward at the same speed as the broken front which forms the bore itself; which in all probability is not very far from the truth. To assist this view, a scale of distances is given on the diagram, which is based upon the average rate of advance of the bore in running up the river.

The bore itself is clearly the broken water at the front edge of a long water-slope which advances up the river. The greatest rate of rise at spring tides after the bore has passed amounts to 3·00 feet in 10m. 5s.; and if we take for the average speed $8\frac{1}{2}$ miles per hour, the equivalent water-slope is 2·10 feet per mile. This slope appears very moderate in the circumstances, although it is really greater than in most rivers, except where rapids occur. Also, as a question of hydraulics, this slope would undoubtedly prove to be in correspondence with the speed of the currents following the bore, if the problem were fully worked out.

It is said that formerly the bore used to be higher than at present, owing to changes that have taken place in the bars in the river, which now obstruct the channel at low water and interfere with its development. No very definite information could be obtained as to this.

On August 22, 1892, a good photograph of the bore was obtained, which has been published in a report of the Geological Survey. Its height as then measured was 5 feet 4 inches. It is clear, from the observations, that in three to four minutes after the bore passes the water has already risen an extra foot. The greatest height which was measured in the above observations was 3 feet 3 inches, although it would be a little higher at the middle of the river. This may probably be taken as a fair average at ordinary spring tides. The maximum no doubt occurs when the moon is in perigee at full or change, and also at its maximum declination, as this gives the greatest difference in favour of one of the two tides in the day. Something also depends on the level to which low water falls, as this practically adds to the height of the bore. The total difference, however, in the level of low water between spring and neap tides, and between one set of spring tides and another, was found to be little more than one foot altogether, as observed in the summer season. Late in the autumn, when the fresh water outflow of the Petitcodiac is increased, the water surface at low tide does not fall so low.

The time of the arrival of the bore, with reference to the time of high water, was worked out from the observations obtained while the tide gauge was being erected. The time of high water at Moncton was obtained by difference of establishment, from the tide tables for St. John. The comparison shows that the time of arrival of the bore varies from 3h. 1m. to 3h. 34m. before the time of high water. This result may, however, be subject to revision.

It is hoped that the arrival of the bore, being a well-defined moment, may serve to throw light on the whole question of the progress of the tide in the Bay of Fundy.

The only other place in the Bay of Fundy at which the bore has been seen is in the upper part of Cobequid Bay. The tide there used to arrive as a bore at Maitland, at the mouth of the Shubenacadie River; but a change in the position of the sand bars below Maitland now prevents this. In running up the Shubenacadie, however, the tide still breaks occasionally into a ripple or miniature bore.

## *THE BOYLE LECTURE ON THE PERCEPTION OF MUSICAL TONE.*

ON Tuesday, June 6, Prof. McKendrick delivered in the Lecture Room of the New Museums, Oxford, the annual Boyle Lecture, the subject being the perception of musical tone. The lecture was entirely devoted to a consideration of the functions of the cochlea, the minute anatomy of which was fully described. The internal ear consists of a complicated series of sacs and tubes filled with fluid. In certain situations the walls of the sacs contain highly differentiated epithelial structures, which are intimately related to the terminal filaments of the auditory nerve. The problem is to explain how the pressures transmitted by the foot of the stapes affect these terminal structures in such a way as to excite sensations corresponding to the pitch, intensity, and quality of tone. The dimensions of the internal ear are so minute as to form only a small part of the wave-lengths, even of tones of high pitch. The nerve endings are still smaller, but they also act as minute portions of any wave, and any reasoning as to the effect of such waves is quite irrespective of the small dimensions of the receiving organs in the internal ear. If we consider a wave of sound as a series of states of condensation and states of rarefaction, travelling on continually in one direction; and, further, if we remember that the motion of each individual particle forming the wave is very small, and is alternately backwards and forwards, in the same line as that in which the wave travels, we see that the movements, inwards and outwards of the base of the stapes, correspond to these oscillations, or, in other words, to increase and diminution of pressure with each wave. Some of the possible movements of the base of the stapes were described, along with their action on the perilymph surrounding the utricle and saccule. We can hear musical tones and noises, we have a peculiar auditory sensation to which we give the name of beats, and we have the power of analysing a musical tone into its component parts. A demonstration was then given of the limits of pitch perception, of beats, and of beat tones. As regards the perception of intensity, the results of inquiries made by Töpler and Boltzmann, and more especially by Lord Rayleigh, showed the delicacy of the ear for sound, as regards energy, is about the same as that of the eye for light. The ear may be affected by vibrations of molecules of the air not more in amplitude than ·0004 mm., or 0·1 of the wave-length of green light; while Lord Rayleigh says "that the streams of energy required to influence the eye and ear are of the same order of magnitude." The question of analysis was next considered, and the bearing on it of Ohm's principle and Fourier's theorem, as regards wave-forms. The lecturer stated that on the whole he was not yet satisfied from any observations he had been able to make that the ear took cognisance of differences of phase, and he pointed out the peculiar difficulties in making observations on this point. He was still inclined to support the views of Helmholtz. Illustrations were given of wave-forms as revealed by the phonograph, and an instrument enabled the audience to hear experiments on pitch, intensity, and quality. Several violin records of rare beauty were reproduced. The lecturer next discussed the probable action of the cochlea. There are only three ways in which the ductus cochlearis, which contains the nerve-endings, may be affected. Either (1) small vibratile bodies may exist between the pressures sent into the organ and the filaments of the auditory nerve, each vibratile body having a frequency period of its own; or (2) individual nerve-fibres may be directly excited by waves of a definite period—that is to say, there may be differences in the nerve-fibres, so that they have a selective action; or (3) the organ may be affected as a whole, all the nerve-fibres being affected by any variations of pressures, and thus the power of analysis, which is admitted, is relegated from the peripheral to the cerebral organs. The first hypothesis seems most probable, for (1) the existence of such bodies would give a natural explanation of many, if not all, of the phenomena; (2) the evidence of comparative physiology points to a gradually increasing complexity in the structure of all the terminal organs of special sense, as there arose a necessity for differentiation and discrimination in the effects of various kinds of stimuli; and (3) investigations into the action of all the sense-organs, such as those of touch and temperature in the skin, of light and colour in the retina, of taste in the tongue, and of smell in the olfactory region—all indicate specialisation of function in the peripheral apparatus. The action of the cochlea was then fully described, and stress was laid on the movements of segments of the membrana basilaris causing contacts between the apices of the hair cells and the under-surface of the membrana tectoria. Suppose that, in accordance with the view of Helmholtz, a segment of the basilar membrane were thrown into sympathetic vibration, it would move in a direction at right angles to the direction of its fibres. These movements would be communicated to the structures lying on its upper surface, and if we suppose the arches of Corti to be elastic, such movements would be transmitted to the hair-cells. These would move in the line of their long axis; in other words, their hairs would move up and down in the meshes of the membrana

reticularis, and strike against the under surface of the membrana tectoria. A reaction would take place from the latter, and thus the delicate nerve-endings between the hair-cells would receive pressures corresponding in frequency to the oscillations of the membrana basilaris. In the cochlea of birds and amphibia, the mechanism is practically the same, but in consequence of the membrana basilaris not being highly differentiated, there cannot be the nice discrimination of pitch of tone which exists in the higher animals. The lecturer gave reasons for holding that a bird has a power of discriminating pitch only through a narrow range. These views were also, on the whole, supported by pathological observations in cases of deafness, and of the deafness of boiler-makers in particular. In the latter there is the loss of perception of high tones, and degenerations are observed in the lower whorl of the cochlea, as is required by theory. The action of the cochlea, as thus conceived, was demonstrated with a model. The lecturer also gave a large number of measurements of parts of the ear, showing that there were a sufficient number of structures in the cochlea to enable us to detect differences of the 1/64th of a semitone, thus amplifying the conclusions reached long ago by Helmholtz. The number of nerve-fibres in each cochlear division of the auditory nerve is about 14,000, giving something like 1250 for each octave through the eleven octaves of audibility. Assuming that the number of auditory filaments is the same for each of the eleven octaves (an unlikely supposition, as there will probably be a larger number of filaments for octaves in the middle of the range of the ear), there will still be two filaments for each 1/64th of a semitone; while, for the same interval, there will be three fibres of the membrana basilaris, and two hair-cells. The production of combination tones, differential and summational, was next considered, the lecturer stating that, in his opinion, and founded on experiment, both had an objective existence. They are not beats, but true sounds superadded to the generators, and thus they fall within the scope of Ohm's law. The theories, other than that of Helmholtz, were then criticised; namely, those of Rutherford, Waller, Hurst, and the more recent one of Max Mayer. The most obvious objection to any theory which dispenses with peripheral analysis is that it leaves the exceedingly elaborate structure of the organ of Corti, and indeed of the cochlea, as a whole, out of account; or, to put the matter in another light, it assigns to that organ a comparatively simple function. Ohm's law also may be subject to certain limitations, but there is no substitute for it. Max Mayer agrees with Hurst in imagining a series of waves transmitted along the scalæ, instead of the scalæ forming part of one wave. The two differ in respect that Max Mayer supposes, on physical grounds, that the amplitude must diminish from base to apex of the cochlea; while Hurst argues, also from the physical point of view, that the amplitude must increase. This is a serious discrepancy, inasmuch as Mayer's theory rests wholly on the supposition of diminished amplitude. It seems impossible to conceive of minute waves following each other in rapid succession in the minute tubes forming the scalæ. These theories are independent of the principle of sympathetic resonance, imperishably associated with the name of Helmholtz, and which still, in the lecturer's opinion, holds the field. Lastly, the lecturer pointed out that the roots of the auditory nerves were probably more widely distributed and had more extensive connections than those of any other nerve. The intricate connections of these nerves were only being unravelled. This pointed to an explanation of how music penetrates to the very roots of our being, influencing by associational paths, reflex mechanisms, both cerebral and somatic, so that there was scarcely a function of the body that might not be affected by the rhthymic pulsations, melodic progressions, and harmonic combinations of musical tones.

## THE DARMSTADT MUSEUM.

THROUGHOUT the civilised world attention is being concentrated on the improvements in the mode of arranging specimens in the exhibition galleries of natural history museums; so that they should be both attractive and instructive to the general public, and at the same time useful to the student. Nowhere does this advance seem more marked than at Darmstadt, where the Director, Dr. G. von Koch, has just published an interesting and well illustrated progress report ("Die Aufstellung der Tiere im neuen Museum zu Darmstadt," Leipsic, 1899.)

We gather from this report that a large proportion of the museum is devoted to the systematic classification of animals; and it is gratifying to observe that not only are skeletons and skulls ranged side by side with the mounted skins, but that anatomical preparations and remains of extinct forms are introduced in their proper serial position. A notable feature (in the seventh gallery) is the exhibition of a series of economic animal products, such as furs, wool, leather, ivory, tortoiseshell, mother-of-pearl, shell, coral, &c. But the greatest novelty is the formation of a gallery (the eighth in the series) illustrating the geographical distribution of animals on the globe. And here, instead of arranging the specimens on the conventional wooden stands on tier upon tier of shelves, an attempt has been made to reproduce the natural surroundings of their habitat.

To take, for example, the South and Central American region, we find, as shown by one of the plates accompanying the report, alligators, tapirs, carpinchos, chajas, &c., occupying the low land by the river. In the adjacent forest tract we have anteaters, sloths, coatis, pacas, opossums, armadillos and the characteristic monkeys. On a higher level we have the open pampas and llanos, with peccaries, brockets, pumas and rheas; while the background of the scene is formed by mountain peaks tenanted by guanacos, vicugnas and condors. Birds of other kinds are likewise introduced in appropriate positions so far as the limits of space permit. Similar scenes represent the other great zoo-geographical regions; and it is important to notice that the whole series is ushered in by the fauna of Hessen-Darmstadt itself.

It would undoubtedly add much to the interest and instructiveness of our own natural history museums if arrangements could be made for the formation of galleries of economic and distributional zoology on somewhat similar lines.

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—A number of the foreign guests who had been present at the Stokes jubilee celebration and the Royal Institution centenary were invited to Oxford on the 8th, and were entertained at a luncheon in Christ Church. Among those who came were Profs. Arrhenius, Barker, Barus, Becquerel, Bleekrode, Ciamician, Cornu, Deslandres, Franchimont, Egoroff, Gautier, Körner, Le Chatelier, Liebreich, Martius, Michelson, Moissan, Nasini, Newcomb, and Sivewright.

In a convocation held the same day, the honorary degree of D.C.L. was conferred upon Profs. Becquerel, Körner, Liebreich, Moissan and Newcomb.

The following were the speeches made by the Regius Professor of Civil Law, Dr. H. Goudy, in presenting them.

Nihil pulchrius nobisque optatius est quam viros e gentibus externis de scientiarum studiis optime meritos societati nostrae adscribi atque arctissimo et dignitatis et amicitiae nobiscum vinculo consociari. Quae res hodie Universitati nostrae contigit quae eos viros, quos mihi adstare videtis, communi omnium ejus membrorum consensu (Instituti quod dicitur Regii annum centenarium feliciter actum commemorans) insigniri jussit.

BECQUEREL.

Primum ad vos duco virum illustrem, Gallica stirpe oriundum, qui in scientia physicae famam eximiam est adeptus, patris in eadem scientia illustris filius. Physicae studiosorum in manibus sunt scripta ejus praeclara principiis scientiae illius illustrandis destinata. Operum numerum quorum auctor doctus ille exstitit referre longum est; neque tamen, ut plurima praeteream, silentio praetereunda videntur opuscula illa, publici juris facta, in quibus de magnetis et electri proprietatibus felicissime disseruit, ipsamque Naturam, rerum creatricem, in lucem proferre coegit quanam ratione quaedam corpora aliquando lumina emittant atque vires electricas eis transmissas per longum tempus retinere possint.

KÖRNER.

Praesento vobis virum egregium, Germanica stirpe oriundum, inter eos qui praecipuam curam rebus chemicis dederunt notissimum. Quantum in ea parte Naturae profecerit, quam multa ingeniose et subtiliter excogitaverit, mihi exponere minime concedit sermonis academici egestas! Quid de compositis aromaticis ab eo recte libratis, quid de ἰσομοιρία, ut Graeco utar vocabulo, corporum in conjunctione naturali disseram?

Audisse sit satis kunc de his studiis ita meritum ut omnibus inter nostrates qui se iisdem studiis maxime devoverint dignus omnimodo laureâ nostrâ videatur.

LIEBREICH.

Salutamus deinceps virum e finibus Germaniae insignem. Ille secreta cerebri feliciter rimatus ad ipsa materiae atoma penetrando phosphorum capitalem Phosphorus et Lucifer ipse clarissimus nobis primo patefecit. Idem acerbissimos animi corporisque dolores impune extinxit,

Spargens chlora venena soporiferumque papaver.

Immo somnum insomnibus attulit, mollem, mortique simillimum.

MOISSAN.

Praesento vobis virum illustrem Lutetiis Parisiorum professorem. Viri hujus ingenium illustre, diligentiam, eruditionem in ea scientia quam ad illustrandam unice se devovit, jamdiu confessi sunt qui eadem in re florentissimi extiterunt. Sed nomini suo immortalitatem quandam justissimo titulo meruisse videtur, invento uno scientiae suae utilissimo; scilicet Fluorii elementum segregando, id quod nulli ante facere contigit, neque sine vitae periculo prioribus constabat experimentum hujusmodi; (scilicet qui sese ante nostrum experimento huic dedicaverant, duo, ante victoriam partam, occubuerunt, lauream tamen reportavit noster, periculo superstes atque, utinam diu superstes sit!)

NEWCOMB.

Sequitur deinceps vir insignis qui trans fluctus Atlanticos transvectus ad nos venit—senex antistes Naturae. Hunc virum scitote per multos annos astrorum motus rationemque coeli ita ingeniose perscrutatum fuisse ut multa non solum nova reperiat sed etiam sermone dilucido expressa argumentis confirmaret certissimis. Idem luminis velocitatem et quantum sol ab orbe terrarum distet singulari curâ investigavit, et tabulas Lunae motus correxit.

"Scire juvat magni penitus praecordia mundi."

At the Encænia, on June 21, the honorary degree of D.C.L. will be conferred upon the Earl of Elgin, Lord Kitchener, Sir Charles Parry, F. W. Maitland, F. D. Godman, Father Ehrle, Cecil Rhodes, and J. G. Frazer.

The eleventh annual report of the delegates of the University Museum (for 1898) is published in the *University Gazette* for June 6. This publication, which increases in dimensions every year, contains the reports of the Regius Professor of Medicine, the Linacre Professor of Comparative Anatomy, the Waynflete Professor of Physiology, the Professor of Human Anatomy, the Hope Professor of Zoology, the Professor of Experimental Philosophy, the Waynflete Professor of Chemistry, the Professor of Geology, and the Waynflete Professor of Mineralogy, and records substantial progress in all these departments.

Mr. E. S. Goodrich has been re-appointed Aldrichian Demonstrator of Anatomy.

Dr. J. F. Payne has been elected a member of the Medical Council of the United Kingdom, in place of Dr. W. S. Church, resigned.

Scholarships in Natural Science are advertised at the following Colleges:—Balliol, November 21; Merton, June 27; New, June 27; Magdalen, October 10; Corpus Christi, June 27; Christ Church, November 21; Trinity, November 21.

On June 14, a statue of Charles Darwin, by Mr. Hope Pinker, which has been presented to the University by Prof. Poulton, will be inaugurated at the University Museum.

CAMBRIDGE.—Mr. H. M. MacDonald, of Clare College, fourth Wrangler 1889, has been appointed University Lecturer in Mathematics in place of Prof. Love, now of Oxford.

Mr. A. E. Shipley, of Christ's College, has been re-appointed University Lecturer in Invertebrate Morphology.

The Adams prize for an essay on the Theory of the Aberration of Light has been divided between Mr. J. Larmor, F.R.S., Fellow of St. John's, and Mr. G. T. Walker, Fellow of Trinity, Senior Wranglers in 1880 and 1889 respectively.

The Smith's prizes for 1899 are adjudged to Mr. W. H. Austin and Mr. G. W. Walker, of Trinity, senior and fourth Wranglers respectively in 1897. Mr. Frankland, of Clare, and Mr. Whipple, of Trinity, receive honourable mention.

Prof. Thomson announces a course of demonstrations in Physics, to be given in the Cavendish Laboratory during the Long Vacation, beginning July 5.

The Council of the Senate propose to expend 125*l*. in preparing an appropriate exhibit for the Educational Exhibitions to be held in London and in Paris in 1900.

The accommodation in the new chemical laboratory is already insufficient for the numbers seeking instruction, and it is accordingly proposed to expend 609*l*. in adapting the attic story as an additional laboratory for elementary students.

The Senior Wranglership this year is divided between Mr. G. Birtwistle, of Pembroke, and Mr. R. P. Paranjpye, of St. John's. Pembroke has had no Senior Wrangler since Sir George Stokes in 1841, and does well thus to mark the year of his jubilee as Lucasian Professor. Mr. Paranjpye is a Mahratta student, who gained numerous distinctions in the University of Bombay before coming to Cambridge: he is the first native of India who has attained the highest mathematical honours. There are forty names (including two ladies) in the list of Wranglers, indicating that the "year" is a strong one.

In Part II., Messrs. Hudson, of St. John's, and Cameron, of Caius, are alone in the First Class (first division). These were senior and second Wranglers respectively in 1898. Miss F. E. Cave-Browne-Cave, of Girton, appears in the third division of the First Class.

In the Mechanical Sciences Tripos, Part I., six students have attained the First Class. In Part II. Mr. B. W. Head, of Emmanuel, has the First Class to himself. Mr. H. E. Wimperis, of Caius, has in the same Tripos qualified for his degree as an "advanced student."

Mr. J. E. Marr, F.R.S., of St. John's, is appointed a member of the General Board of Studies, in place of Dr. Langley, resigned.

Dr. D. MacAlister, Mr. C. E. Grant, and Mr. C. Warburton are appointed members of the new Board of Agricultural Studies.

---

WE learn from *Science* that Dr. C. E. Beecher, professor of historical geography in Yale University, has been appointed to succeed the late Prof. O. C. Marsh as Curator of the geological collections of the Peabody Museum.

THE Education Department has received from Berne an announcement that an educational exhibition will be held in that city next autumn. The authorities organising the exhibition will welcome exhibits illustrating education in this country. Communications from those willing to take part in the exhibition should be addressed to the Director, Schweizerische Permanente Schulausstellung, Berne, from whom further particulars can be obtained.

WITH a view to assisting teachers of schools and classes to acquaint themselves with the methods and principles of natural science, especially as bearing upon aspects of school and class work, the Technical Instruction Committee of the Liverpool City Council have made arrangements with Prof. W. A. Herdman, F.R.S., Professor of Zoology at University College, to give a short course of lectures and laboratory demonstrations on the study of natural history.

IT has already been pointed out in these columns that the appointment of particular authorities to be responsible for technical and secondary education within their districts will reduce the overlapping which at present exists in many places. The London County Council was recently appointed as the sole authority to distribute the Science and Art grant in London, and as such it has taken exception to certain items of expenditure by the London School Board on technical or secondary education, on such lines as to compete injuriously with similar work in the Council's polytechnics and institutes in the same districts. The *Times* reports that the Local Government Board auditor has now ruled that such expenditure by the School Board is illegal, and can only be carried through as financial aid from the County Council. It is stated that the London School Board will appeal against this decision. Meantime, it is understood that the ruling will apply, not only to the London Board, but also to other School Boards throughout the country.

SOME statistics relating to engineering education are given by Dr. M. E. Wadsworth in a paper published in the *Transactions* of the American Institute of Mining Engineers. Engineering education in the United States has been, on the whole, a thing of comparatively recent date—the pioneer schools being the Rensselaer Polytechnic Institute, established in 1824; the Lawrence Scientific School, dating from 1846; and the Sheffield School, from 1847. But little further prominent work was done until 1863, when the Columbia School of Mines was established and followed rapidly by numerous other engineering schools,

The tables given by Dr. Wadsworth are not complete, but so far as they go they show that "in mining engineering the leading schools in the world, so far as shown from the records here published, are Freiberg, Leoben, Clausthal, Berlin, Paris, St. Etienne, Schemnitz, Przibram, Michigan College of Mines. California, Columbia, Lehigh, Massachusetts Institute of Technology, and Colorado."

AN account of the proposed Institute of Scientific Research for India, which Mr. J. M. Tata, of Bombay, has undertaken to endow with an annual income of a lakh and a quarter (125,000 rupees), is given by Sir Henry Acland in the second edition of his little volume, "Medical Missions in their Relation to Oxford" (London: Henry Frowde). As already announced, it is intended to found an institution which shall be, or correspond to, a Teaching University for India, concerning itself principally with post-graduate studies and scientific research. A committee has been organised to take the matter in hand and appeal for funds; and Mr. Tata's commissioner, Mr. B. J. Padshah, is making inquiries in Great Britain, in Europe, and in the United States, how best to carry out the scheme. Sir Henry Acland utilises the opportunity which the proposed scheme affords to accentuate his appeal that "a generous benefactor, or some great National Company, should complete in Oxford the Public Health Department for University Education in the subject of public health and anthropology, with special reference to Mr. Jamsetji M. Tata's great scheme for natural science in general, and sanitary science in particular, in India."

AN exhibition of practical work executed by candidates at the recent examinations of the City and Guilds of London Institute was opened at the Imperial Institute, on Friday, by the Duke of Devonshire. Referring to the character of the instruction given under the direction of this institute, His Grace remarked: The object of this instruction is to familiarise a student with all the processes and all the details the use of which is required in the trade he is going to undertake, and to show to him how the knowledge he has acquired in lectures or in books may be applied to the practical performance of his business. This exhibition, I hope, will help those who see it to realise the real need of the technical instruction now being given. If you sent students direct from the classes of the Science and Art Department into a workshop they would be utterly incapable, in all probability, of applying in a practical way the knowledge which they have acquired in the classes. If you separate by too long an interval the lecture-room from the workshop, the work will be lost, but if you combine the lecture-room with the workshop, you have the material from which we may reasonably expect that expert finished artisans will be provided, although, of course, perfect workmen can only be produced by long and continuous practice. The artisan students in the registered classes of the institute now number over 34,000, in addition to nearly 2000 students in its manual training classes, and of these numbers 13,800 were examined last year, showing an increase of 800 over any previous number.

## *SOCIETIES AND ACADEMIES.*

### LONDON.

**Royal Society**, April 20.—"Note on the Fertility of different Breeds of Sheep, with Remarks on the Prevalence of Abortion and Barrenness therein." By Walter Heape, M.A., Trinity College, Cambridge. Communicated by W. F. R. Weldon, F.R.S.

The paper is a brief abstract of information obtained from 397 sheep-breeders, who have supplied records of flocks containing 122,673 ewes for the breeding season of 1896–7.

The information obtained referred especially to the following eight pure breeds of sheep: Suffolk (7506 ewes), Kent (9931), Southdown (9134), Hampshire (26,400), Oxford Down (3555), Dorset Horn (10,285), Shropshire (8492), Lincoln (17,880). Besides these, returns were received for a small number of flocks for each of ten other pure breeds, referred to below as "various pure breeds" (10,010), and for certain cross-bred flocks (19,480).

*Fertility.*—The importance of fertility as a factor in the survival of a species is referred to, and some of the influences attending domestication which tend to reduce that importance are pointed out. Reference is made to Prof. Karl Pearson's account of the racial characteristic of fertility in the human species, and it is demonstrated that, in spite of the equalising effects of domestication, fertility in different breeds of sheep is also of a racial character.

Owing to the fact that the returns supplied by flock-masters of the number of lambs born are admittedly not always correct, and in view of the fact that the record of twins produced is considerably more accurate, statistics of the latter have been chiefly utilised for generalisations regarding fertility. These records show that the pure breeds dealt with stand in the following order:—

Suffolk (52·22 per cent. of twins), Shropshire (46·84), Dorset Horn (37·55), Oxford Down (35·02), Kent (31·38), Lincoln (29·09), various pure breeds (28·09), Hampshire (24·09), Southdown (18·67); that the average percentage of twins for these breeds is 30·02; and that the cross-bred flocks produce 31·04 per cent. of twins.

From this return, it is seen that the value of the Suffolk and Shropshire breeds, as prolific breeds, is incontrovertible, while the records of the Southdowns is so low as to show urgent need for close attention to the subject on the part of breeders. It is to be noted that several of the pure breeds show a higher rate of fertility than the cross-bred flocks.

The fertility of certain of the pure breeds is then examined with regard to locality, and it is demonstrated that while locality may affect the fertility of a breed, it does not do so to a sufficient extent to alter the racial characteristic of the fertility of the breed. The chief possible exception to this is found among flocks of Lincoln sheep kept in Yorkshire, in which the percentage of twins recorded is practically double the percentage obtained in the home county; but it is pointed out that, in this case, there are circumstances which indicate the difference is due to an abnormally low percentage of fertility in the Lincolnshire rather than to an especially high rate of fertility in the Yorkshire flocks.

The influence of management, of the condition, kind and amount of food available, of the season, weather, subsoil, and the age of breeding ewes upon the fertility of a flock was referred to.

Considering the percentage of lambs produced by the pure-bred flocks individually, it is seen that the percentage ranges, in 306 flocks, from 203·8 to 59·09 per cent., the most frequent percentage being between 110 and 120 per cent.

As regards the different breeds, the most prominent points demonstrated by this inquiry are the value of the Suffolk breed from a point of view both of fertility and low rate of loss from abortion and barrenness; the unsatisfactory condition of Southdowns, both as regards fertility and loss; the urgent need for investigation of the fertility of Dorset Horn ewes with rams of their own breed; and of the conditions affecting both fertility and loss in flocks of Lincolns in the home county.

**Physical Society**, June 9.—Prof. Lodge, President, in the chair.—The Secretary read a paper, by Mr. C. G. Lamb, on the distribution of magnetic induction in a long iron bar. A Lowmoor iron rod, whose length was 250 times its diameter, was taken, and a B–H curve plotted by ballistic measurements made with a search coil at the centre of the bar. The search coil was then moved along the bar, and the distribution of induction was determined for magnetising forces varying from $H = \cdot 74$ to $H = 35 \cdot 0$. Up to fields of 3·35 the induction leaks out more and more quickly as H increases, but above this value the induction tends to keep in more and more. From the curves obtained, the mean induction was deduced as well as the distance of the resultant pole from the middle of the bar. It is shown that this distance first decreases and then increases with the rise in field strength. According to the ellipsoidal theory, it should be constant. The bar was then made into a ring, and the B–H curves again determined. From these curves, together with known relations between B, H and $\mu$, curves showing the variation of $\mu$ along the bar were constructed. The Chairman gave a general explanation of the way the leakage depended upon the permeability in the case of a long iron bar.—A paper on the absolute value of the freezing point was read by Mr. Rose-Innes. The corrected values of the absolute value of the freezing point determined by Lord Kelvin from experiments on hydrogen air and carbonic acid contain discrepancies amounting to 1/3 per cent. between the carbonic acid and the hydrogen, while the separate measurements for carbonic acid agree among themselves to about 1/6 per cent. Starting with Lord Kelvin's equation for the forcing of a gas through a plug, the author has obtained a formula for the ab-

solute value of the freezing point, which can be worked out from the experimental researches of Regnault. The formula is based on the experimental proof by Joule and Kelvin, that the ratio between the cooling effect per atmosphere of differential pressure and the pressure is constant for all pressures. Applying data from Regnault's experiments to the formula deduced by the author, the values of the freezing point are practically the same as those given by Lord Kelvin. Hence it is thought probable that the discrepancies are due to inaccuracies in the experiments of Regnault which were conducted at constant pressure. The value of the zero calculated from experiments on hydrogen at constant volume made by M. Chappuis is, if we treat hydrogen as a perfect gas, 273·034. Applying a thermodynamic correction for the deviation of hydrogen from the laws of a perfect gas, the value of the freezing point becomes 273·19. This figure agrees very closely with the value 273·14 obtained by Lord Kelvin from the constant pressure experiments on air. The correction has only been applied to hydrogen, because in this case it is so small that a large percentage error in its determination has a very small effect upon the absolute value of the freezing point. In constant pressure work the experiments are difficult to carry out, and the correction is easily applied, while in constant volume work the experiments are easily performed, and the thermodynamic correction is difficult to apply. Prof. Gray expressed his interest in the manner in which Mr. Rose-Innes had obtained his results without using the experimental data of Joule and Kelvin, and pointed out that Lord Kelvin attached most importance to the results he had obtained for air. It would be useful to have the gas constants redetermined with greater accuracy. The compensating arrangement devised by Prof. Callendar would enable experiments at constant pressure to be carried out satisfactorily. Dr. Lehfeldt drew attention to the sign of the correction applied by the author, and asked if it should not be negative instead of positive. He pointed out that variation in the specific heat of a gas might affect the formula, and said that Boltzmann had shown that it was impossible to determine an absolute temperature without introducing calorimetric measurements. As Joule and Kelvin had sometimes found positive and sometimes negative values for the cooling effect in the case of hydrogen, large percentage errors might occur in the value of the correction. Mr. Blakesley asked what the probable error was in the numbers given by Lord Kelvin. Mr. Watson said that the author had calculated the value of the freezing point from experiments on hydrogen, and had shown that the result agreed closely with the value of the zero deduced by Lord Kelvin from experiments on air. He would like to know what agreement would be got by applying Mr. Rose-Innes' correction to the case of air. Mr. Rose-Innes, in replying, said he agreed with Prof. Gray that it would be useful to have the constants redetermined. It was only in their early work that Joule and Kelvin observed a cooling effect for hydrogen, the bulk of the experiments giving a heating effect. The sign of the correction depended on the increase or decrease of the effect with temperature, and was positive in the case of hydrogen. Regnault has proved experimentally that the value of the specific heat is constant.

**Chemical Society**, June 1.—Dr. W. H. Perkin, Vice-President, in the chair.—The following papers were read :—The hydrosulphides, sulphides and polysulphides of potassium and sodium, by W. P. Bloxam. The author has prepared substances of the following compositions :—

$$K_2S,2H_2O;\ K_2S,5H_2O;\ K_2S,12H_2O;\ Na_2S,9H_2O;$$
$$2KHS,H_2O;\ NaHS,2H_2O;\ NaHS,3H_2O;\ K_4S_5,10H_2O;$$
$$K_4S_8,6H_2O;\ K_4S_8,19H_2O;\ K_4S_9,xH_2O;\ K_4S_{10},xH_2O;$$
$$\text{and } Na_4S_9,14H_2O.$$

—On the relative efficiency of various forms of still-head for fractional distillation, by S. Young. The author has tested the efficiency of a number of forms of still-head in common use, and has devised new forms of greater efficiency.—The salts of dimethylpyrone and the quadrivalence of oxygen, by J. N. Collie and T. Tickle. The authors consider that dimethylpyrone chloride contains tetravalent oxygen, and has the following constitution :—

$$O{=}C\left\langle\begin{matrix}CH{:}CMe\\ CH{:}CMe\end{matrix}\right\rangle O\left\langle\begin{matrix}H\\ Cl\end{matrix}\right. .$$

—The symmetrical di-isopropylsuccinic acids, by W. A. Bone and C. H. G. Sprankling. By the action of isopropyl bromide on ethyl sodioisopropylcyanosuccinate and subsequent hydrolysis of the ethereal salt produced, the authors have obtained *cis*- and *trans*-di-isopropylsuccinic acid ; the dissociation constants have been determined.—Active and inactive phenylalkyloxyacetic acids, by A. McKenzie. Phenylalkyloxyacetic acids, in which the alkyl group is either ethyl, methyl, propyl or isopropyl, have been prepared from lævo and inactive mandelic acid ; in some cases racemation occurs.—The chemical composition of the oleo-resin of *Dacryodes hexandra*, by A. More. The oleo-resin of *Dacryodes hexandra* contains lævopinene, lævosylvestrene, a resin and a white crystalline substance which is probably ilicic alcohol.—The condensation of ethyl acetonedicarboxylate : the constitution of triethyl orcintricarboxylate, by D. S. Jerdan. The author has obtained a diethyl orcintricarboxylate as a new condensation product of ethyl acetonedicarboxylate ; the diethyl- and triethyl-salt both yield derivatives of two orcindicarboxylic acids, so that the constitution of triethyl orcintricarboxylate is determined.—A series of substituted nitrogen chlorides, by F. D. Chattaway and K. J. P. Orton. The authors have prepared a number of substituted nitrogen chlorides by aid of a reaction represented by the following equation :—

$$\left.\begin{matrix}R.CO\\ R'\end{matrix}\right\rangle NH + HOCl = \left.\begin{matrix}R.CO\\ R'\end{matrix}\right\rangle NCl + H_2O.$$

**Royal Microscopical Society**, May 17.—Mr. E. M. Nelson, President, in the chair.—Mr. C. L. Curties exhibited and described a new electrically heated stage for the microscope, made by Reichert. It was constructed so as to be heated by the current from the ordinary electric lighting supply. By an ingenious automatic arrangement the stage could be maintained at any required temperature to within 0·1° C.—Messrs. Watson and Sons exhibited a form of dissecting stage, designed by Mr. T. G. West, which could be used with any microscope without damaging the stage of the instrument when doing rough work.—The President called attention to some beautiful photographs of Mr. Grayson's rulings, taken by Mr. Wedeles.—Dr. Sorby's communication not being forthcoming, the President read a paper on the fine adjustment. He described the various forms which had been adopted from time to time, and said that in the course of his investigations he had discovered that Varley's inventions had been ascribed to others, and that the long lever fine adjustment generally ascribed to Ross was really first made by Powell.—The President then called attention to the exhibition of "pond life" by Fellows of the Society and Members of the Quekett Microscopical Club.

PARIS.

**Academy of Sciences**, June 5.—M. van Tieghem in the chair.—On the development in series of the integrals of differential equations by Cauchy's method, by M. Émile Picard.—Remarks on the formation of alcohol and carbonic acid, and on the absorption of oxygen by the tissues of plants, by M. Berthelot. Some remarks on a note in the previous number of the *Comptes rendus*, by M. A. Devaux. M. Berthelot recalls some experiments on the formation of alcohol made by him in 1860, and emphasises the necessity of very careful manipulation in experiments of this nature. Thus the alcohol may be driven off by a current of hydrogen at 110°, if the carbon dioxide is to be determined, or in a rapid current of steam if the isolation of the alcohol only is aimed at. If the manipulation of the leaves is not carried out as rapidly as possible, alcohol is readily formed during the process.—On the molecular refractions, molecular dispersion, and specific rotatory power of the combinations of camphor with some aromatic aldehydes, by MM. A. Haller and P. Th. Müller. The substances studied would be represented by the general formula

$$C_8H_{14}\left\langle\begin{matrix}C{=}CHR\\ |\\ CO\end{matrix}\right. ,$$

where R was $C_6H_5$, $C_6H_3O_2CH_2$, $C_6H_4(C_3H_7)$, and $C_6H_4(OCH_3)$. The results of the experiments are given in a table showing the molecular refractions of each of these substances for the rays Na, $H_\alpha$, $H_\beta$, $H_\gamma$, the molecular dispersion, and the specific rotatory power $(\alpha)_D$ at 20°, all determined in toluene solution. Both the molecular refractions and dispersions deviate strongly from the values calculated from the usual moduli, and this peculiarity is still more marked in the specific rotatory power, which for camphor is about 42°, and for these aldehyde camphors is of the order of 500°.—Construction of a plane mirror of 2 mètres diameter by mechanical methods, by M. P.

Gautier.—Stellar photographs taken with the large telescope of the Observatory of Meudon, by M. H. Deslandres. The telescope used had a great focal length (25 times the aperture, 60 cm.); the photographs taken of the moon, Jupiter, Saturn, and nebulæ are said to compare well with the earlier work of Pickering, Scheiner, and Lord Rosse.—Remarks on the preceding communication, by M. J. Janssen.—On the determination of reference points in the spectrum, by M. Maurice Hamy.—On indeterminate equations of two or three variables which have only a finite number of solutions in prime numbers, by M. Edmond Maillet.—On the partial differential equations of the second order with real characteristics, by M. J. Coulon.—On the calculation of the constant of rectilinear diameters, by M. E. Mathias. The method given for the determination of the constant $a$ is applied to the observations of Knietsch on chlorine. The value of the constant in this case is 0·5872, showing that the assumption made by Thorpe and Rücker that $a = 1$ is wanting in generality.—New galvanometric method, by M. Féry. When the torsional couple acting on the suspended portion of the galvanometer is weak, considerable uncertainty is introduced into the results by the uncertainty of the zero. By measuring the angular velocity with which the suspended system starts off, this difficulty is avoided.—On the use of potassium chlorate in explosives of the ammonium nitrate class, by M. H. Le Chatelier. From a solution containing potassium chlorate and ammonium nitrate, crystals of very constant composition and containing 5 per cent. of the former salt can be separated by modifying the temperature and composition of the mother liquor. These crystals, used instead of pure ammonium nitrate in safety explosives, have a greater certainty of detonation.—On the effect of low temperatures upon certain steels, by M. F. Osmond. The results of the experiments upon certain alloys of nickel and iron are in general agreement with those of Dewar and Fleming upon the same subject, the steel acquiring magnetic properties at the temperature of liquid air.—Action of phosphoretted hydrogen upon copper, cuprous oxide, and ammoniacal solutions of copper salts, by M. E. Rubénovitch. Metallic copper reacts with $PH_3$ at 180°–200° giving hydrogen and $Cu_3P$. Cuprous oxide reacts with the same gas at ordinary temperatures, giving the same copper phosphide and water. Various salts of copper, if treated in ammoniacal solution with hydrogen phosphide, behave differently according to the nature of the salt.—On the aloins, by M. E. Léger. Two distinguishing tests are given for barbaloin, and several derivatives are described prepared from the aloes of Natal.—On some derivatives of the unsymmetrical tetra-methyl-diamido-diphenylethane, by M. A. Trillat.—Study of some substituted diphenyl-anthrones, by M. L. Tétry.—On some colour reactions of the oxycelluloses, by M. Edm. Jandrier.—Contribution to the study of mineral waters: on the Croizat spring, near Mont Dore, by M. F. Parmentier. The results of an analysis of the water are given. Iron is absent, but salt and arsenic are present in notable quantities.—On mineral waters containing fluorine, by M. Parmentier. The waters analysed by the author contain no trace of any fluorine compound.—Modification of the respiration of plants produced by varying the temperature, by M. W. Palladine.—On the systematic position of *Trichophyton* and neighbouring forms in the classification of fungi, by MM. L. Matruchot and Ch. Dassonville.—The coal-bearing strata of the central Pyrenees, by M. Caralp.—Concerning the effect of blood serum in preventing the action of rennet, by MM. L. Camus and E. Gley. Reclamation of priority against M. A. Briot.—Coagulating action of the liquid from the external prostate of the hedgehog on the contents of the seminal vesicles, by MM. L. Camus and E. Gley.—Bunge's law, and the mineral composition of the newly-born infant, by M. L. Hugounenq.—Lesions of the nervous centres in experimental epilepsy of absinthe origin, by M. G. Marinesco.

## DIARY OF SOCIETIES.

*THURSDAY*, JUNE 15

ROYAL SOCIETY, at 4.—Prof. A. Michelson will read a Paper.—A Comparison of Platinum and Gas Thermometers at the International Bureau of Weights and Measures at Sèvres: Dr. J. A. Harker and Dr. P. Chappuis.—A Preliminary Note on the Life-History of the Organism found in the Tsetze Fly Disease: H. G. Plimmer and Dr. J. Rose Bradford, F.R.S.—The Colour Sensations in Terms of Luminosity: Captain Abney, F.R.S.—On a Quartz-Thread Gravity Balance: R. Threlfall, F.R.S.—On the Orientation of Greek Temples, being the Results of some Observations taken in Greece and Sicily in May 1898: F. C. Penrose, F.R.S.—And other Papers.

LINNEAN SOCIETY, at 8.—Contributions to the Natural History of Lake Urmi and its Neighbourhood: R. T. Günther.—A Systematic Revision of the Genus Najas: Dr. A. B. Rendle.—On the Anatomy and Systematic Position of some Recent Additions to the British Museum Collection of Slugs: Walter E. Collinge.—The Edwardsia Stage of Lebrunia, and the Formation of the Œsophagus and Gastro-cœlomic Cavity: J. E. Duerden.

CHEMICAL SOCIETY, at 8.—Ballot for the Election of Fellows.—On the Decomposition of Chlorates, with special reference to the Evolution of Chlorine and Oxygen: W. H. Sodeau.—The Action of Hydrogen Peroxide on Formaldehyde: Dr. A. Harden.—Homocamphoronic and Camphononic Acids: A. Lapworth and E. M. Chapman.—Action of Silver Compounds on α-Dibromocamphor: A. Lapworth.—The Colouring Matter of Cotton Flowers: A. G. Perkin.—Experiments on the Synthesis of Camphoric Acid: H. A. Auden, W. H. Perkin, jun., and J. L. Rose.—Methylisoamylsuccinic Acid, Part I.: W. T. Lawrence.

*SATURDAY*, JUNE 17.

GEOLOGISTS' ASSOCIATION.—Excursion to Lichfield and Cannock. Directors: Prof. C. Lapworth F.R.S., and Prof. W. W. Watts.

*MONDAY*, JUNE 19.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Exploration between Lake Rudolf and the Nile: Colonel J. R. L. Macdonald, R.E.

VICTORIA INSTITUTE, at 4.30.—Address by the Right Hon. Sir Richard Temple, Bart.

*TUESDAY*, JUNE 20.

ZOOLOGICAL SOCIETY, at 8.30.—On the Species of Cassowaries: Hon. Walter Rothschild.—On the Remains of a New Bird, *Praphaethon shrubsolei*, gen. et sp. nov., from the London Clay of Sheppey: C. W. Andrews.—On the Antipatharian Corals of Madeira: J. Y. Johnson.

MINERALOGICAL SOCIETY, at 8.—On the Constitution of the Mineral Arsenates and Phosphates. III. Plumbogummite and Allied Minerals: Mr. Hartley.—Note on Plumbogummite: Prof. Miers.—On a Pyroxene from South Africa: Mr. Bowman.—On the Chemical Composition of Tetrahedrite: Messrs. Prior and Spencer.—(1) On a Constituent of the Meteoric Iron of Youndegin, Western Australia; (2) On the Meteoric Stones which fell at Mount Zomba, British Central Africa, on January 25, 1899: Mr. Fletcher.

ROYAL STATISTICAL SOCIETY, at 5.—The Flag and Trade: A. W. Flux.

ROYAL PHOTOGRAPHIC SOCIETY, at 8.—Retouching: Redmond Barrett.

*WEDNESDAY*, JUNE 21.

GEOLOGICAL SOCIETY at 8.—Agglomerates, Ashes, and Tuffs in the Carboniferous Limestone Series of Congleton Edge: Walcot Gibson and Wheelton Hind.—Ironstone Fossil Nodules of the Lias: E. A. Walford.—Additional Notes on the Glacial Phenomena of Spitsbergen: E. J. Garwood.

ROYAL METEOROLOGICAL SOCIETY, at 4.30.—Heavy Falls of Rain recorded at the Observatories connected with the Meteorological Office, 1871–98: Robert H. Scott, F.R.S.—Average Height of the Barometer in London: R. C. Mossman.—A New Self-recording Anemoscope: Joseph Baxendell.

ROYAL MICROSCOPICAL SOCIETY, at 8.—Notes on some Sponges belonging to the Clionidæ obtained at Madeira: J. Y. Johnson.

## THE EXPERIENCES OF A ZOOLOGIST IN AUSTRALASIA.

*In the Australian Bush, and on the Coast of the Coral Sea: being the Experiences and Observations of a Naturalist in Australia, New Guinea, and the Moluccas.* By Richard Semon. With 86 illustrations and 4 maps. Pp. xv + 552. (London: Macmillan and Co., Ltd., 1899.)

ZOOLOGISTS have during the past few years reaped the benefit of Dr. Semon's travels in Australasia and in the Malayan Archipelago in the beautifully illustrated series of memoirs entitled "Semon, Zoologische Forschungsreisen in Australien und dem Malayishen Archipel," and published as part of the *Jena Denkschriften.* Five quarto volumes have already been published, running to some 1600 pp. and 113 plates, many of which are coloured. They contain memoirs on Ceratodus, Monotremes, Marsupials, Manis, the Dugong and other vertebrates, as well as important communications on various invertebrates; most of these have been contributed by well-known European specialists, Dr. Semon himself being responsible for the monographs on the development of Ceratodus, and of the Monotremes and Marsupials.

The large collections made by Dr. Semon having been carefully conserved, they have contributed considerably to our knowledge of tropical life from an anatomical as well as from a faunistic point of view.

On glancing over this monumental series of memoirs one is struck by the amazing activity of Dr. Semon both in the field and in the laboratory, and all zoologists must once more feel grateful to Dr. Paul von Ritter for his princely liberality in the cause of science.

But Dr. Semon has given us further cause for gratitude, as he has narrated his varied experiences of travel, and has recorded numerous observations on the habits of animals that would either have been unrecorded or buried in the obscurity of a technical treatise. More than this, Dr. Semon is not tainted with that half-cynical *fin-de-siècle* spirit which is too rife at present even amongst scientific men. There are men who appear to be ashamed of the interest they take in their own work, and who freeze younger men with a smile. The author of "In the Australian Bush," on the contrary, is not only a trained laboratory student, but he is a field naturalist as well. He revels in the varied aspects of nature, whether it be the monotonous Australian bush or a glorious tropical jungle, and he is not ashamed to let the reader share his joy and enthusiasm.

Dr. Semon left Europe in the summer of 1891 (in the preface it is 1892) for the purpose of collecting embryological material of the more interesting Australasian animals, and proceeded at once to the Burnett River; for it is only in the river systems of the Burnett and the Mary in South Queensland (latitude 25° to 26° S.) that the unique Ceratodus lives. This restriction of habitat is due to its avoidance of river heads, so that it cannot get conveyed by floods across a watershed; its being easily affected by sea-water, so that migration through the mouths of streams is impracticable; and to the eggs being so frail and tender that they cannot bear the most transient drying. Its survival in the Burnett and Mary Rivers is probably owing to some particularly extensive water-holes; should these ever dry up, this remarkable "living fossil" would become extinct. The fish is perfectly helpless out of the water, which it never leaves; neither does it form a cocoon, or indulge in a summer sleep like its African cousin Protopterus. The lungs enable it, by respiring air, to exist in the dry season in water-holes that are crowded with refugees from the river, and which soon become putrid by rotting animal and vegetable substances. Dr. Semon was greatly hindered in his collecting of embryological material by heavy floods, so he returned the following season, and was rewarded by obtaining a complete series of eggs and larvæ.

Of the habits of the Platypus (Ornithorhynchus), and especially of the Echidna, we have several interesting observations. A considerable number of eggs and embryos were obtained, and as much adult material as Dr. Semon cared to preserve. As the book is not intended for specialists, the author gives only sufficient anatomical information to enable the reader to appreciate the importance of his investigations, and all through the book we have short expositions of local problems of the geographical distribution of animals, which should enable the non-scientific reader to appreciate the chief reason why field-naturalists make such large collections.

Although most of Dr. Semon's investigations were concerned with land animals, he did some marine work in the Moluccas, where he went on a fruitless quest for the eggs of the nautilus during the months of January and February (1893). When at Ambon (the Amboyna of the Portuguese) he found that the nautilus is very rarely caught during the north-west monsoon, but that it was not unfrequently found during the south-east trade-wind. Two other instances have been observed by Dr. Semon of a periodical migration of marine animals from deep to shallow water for the purpose of depositing their eggs. The first was at Heligoland, in the case of the common starfish (*Asterias rubens*); the second was at Ambon, where the brilliantly coloured, flexible sea-urchin (*Asthenosoma urens*) wanders into shallow water only during the south-east monsoon. Interesting observations are recorded of the means by which sea-urchins are protected against the attack of certain rapacious marine snails that can spurt free sulphuric acid from their mouths in order to dissolve the calcareous spines and shells of these armoured echinoderms.

The natives of the various countries which Dr. Semon visited also attracted his attention, and he has given us his impressions in a pleasant manner; but he is less trustworthy when he passes from his own observations to general statements. For example, he says, "by far the most of the Queensland and New South Wales tribes are entirely devoid of religion" (p. 223). On the preceding page he asks, "Can one speak of religion to a people whose language possesses hardly any words for abstract expressions, and who have no sort of worship for any supernatural being, idolatry, sacrifice, and prayer being things unknown throughout Australia?" Worship of a supreme being, idolatry, and sacrifice may be unknown

in Australia; but Howitt wrote fifteen years ago (*Journ. Anth. Inst.*, xiii. p. 459), "I venture to assert that it can no longer be maintained that they have no belief which can be called religious." It is probably more correct to say that religion is intimately connected with nearly every act of the daily life of the Australian aborigine than to deny its existence.

While Dr. Semon gives a vivid account of the natives on the coast of British New Guinea from Yule Island to South Cape, he inadvertently falls into a few errors. It is true that the cranium of the Papuan is decidedly dolichocephalous in certain regions, but along the coast visited by Dr. Semon brachycephalism is almost as common as the other extreme. On more than one occasion the petticoats of the women are said to be made of coco-nut fibre, whereas this is never employed; the shredded leaf of the sago palm, however, is a very favourite material.

In the account of the murder of George Hunter by his native wife and her accomplices, the impression is given that the wife was entirely to blame. There is another version to this story, which is supported by the petition of the white ladies residing at Port Moresby for the free pardon of the wife. Although, as Dr. Semon is aware, the bow is not used by natives south of Port Moresby, he speaks (p. 373) in general terms for the "whole of South New Guinea" of birds of paradise being killed by "well-directed arrows." But on the whole there are few mistakes, and only a small number of verbal misprints. The general impression created by the book is correct, and the author's personal attitude towards the natives is most commendable. He refers in a kindly spirit to the excellent missionaries of varied creed, and is justly loud in his praises of the administration of Sir William Macgregor.

The illustrations, as a rule, are not particularly good, the views being reproduced from touched-up photographs; but for this there is a valid excuse, as the camera Dr. Semon took out with him did not stand the climate. Most of the figures of animals are evidently process blocks from pen and ink drawings, and they are somewhat hard and flat. There must necessarily be some defects in a book of travels, and especially in one which embraces so many subjects as this does; but the present writer would rather insist on the real excellence of the book, which has recalled happy memories of many similar experiences.

## AMERICAN NATURAL HISTORY.

*Chapters on the Natural History of the United States.* By R. W. Shufeldt. Pp. 480. Illustrated. (New York: Studer Brothers, 1897.)

ALTHOUGH bearing on its title-page the date 1897, for some reason or other copies of this work appear only recently to have been received in this country; and in reading the volume it is important that the date of publication should be borne in mind, as otherwise certain statements might be taken to indicate that the author was somewhat behind the time.

As a technical worker in several branches of zoology, Dr. Shufeldt has attained a well-merited reputation on both sides of the Atlantic; but, like many other naturalists of position, he is not above putting the results of some of his investigations and studies in popular form for the benefit of the "man in the street." And the present handsome and beautifully illustrated volume is in the main a reproduction of popular articles on various branches of natural history which appeared in American periodicals. Whenever he considered it necessary, the author has, however, made corrections and additions to the original text in order to bring it up to date. Although the greater portion of the matter relates to birds, the work naturally covers a wide field. We have, for instance, in addition to those on ornithology, chapters on the methods of study of natural history, classification of mammals, crayfish and crabs, sawfish, rays, and sharks, whales and manatees, various rodents, and bats and their habits. And in each and all of these the same level of interest, combined with instruction, that characterises the first is fully maintained.

Over many of his fellow naturalists, at least in Europe, Dr. Shufeldt has a very great advantage from the fact that he is an accomplished artist, both with the pencil and the brush, while he also makes full use of the camera. And in the first chapter of the volume he urges the extreme importance of the artistic power in the making of a good naturalist. Possibly he may lay an undue stress on the value of this capacity, but there can be no question that the "artistic eye" affords a guide in the correct diagnosis of allied animals that nothing else can replace.

And here it may be well to draw attention to the thoroughness of the author's methods of research, and the importance attached by him to observations in the field. The following, for instance, he gives as the method of procedure for a naturalist to adopt in describing an animal:—

"Having obtained all the possible light upon its habits in nature, and its geographical distribution, and every fact and fiction that has appeared in regard to it in literature—then seize upon all the material obtainable, enough in any event in order to fully exhibit the extremes of variation in size; the sexual characters; the eggs, embryos, and young at all stages; the fossil forms, if any are known; and finally, an abundance of similar material representing all the apparent allies of the particular form, either near or remote."

Then the specimens are to be examined anatomically, both macroscopically and microscopically.

"Having accomplished all this, we are prepared to use our laboratory notes in writing out an account of the species; naming it if the form be unknown to science; and suggesting a place for it in the system."

With such detail in his mode of working, Dr. Shufeldt, it is almost needless to say, is not a "species-maker."

And in this connection his opinion in regard to the species-making now going on in the States should certainly be quoted. When writing of the common chipmunk, for instance (p. 405), he says:

"Some of the other forms resemble it quite closely, while others depart more or less from it in the matter of size and coloration; some are distributed over a considerable geographical area, others being more or less restricted in their ranges, thus offering descriptive zoologists abundant opportunities to describe the fine

intergrading forms as new sub-species, an opportunity that has been fully availed of by a few ambitious mammalogists more anxious to add to a personal reputation than to be of any special use or aid to the science which they pretend to advance."

This is strong language, but there seems, in some instances, considerable justification for its use.

Of one of the above-mentioned chipmunks, a life-sized figure is given, which may be taken as a good example of the author's own sketches. Excellent as is this figure from a zoological standpoint, it cannot however compare in artistic effect with the reproduction of a photograph taken by the author of the deer-mouse (*Peromyscus leucopus*), which is perhaps the most exquisite in the whole book. The little creature is represented issuing from a maize-cob, on which it has been making a meal, and the half-frightened, stealthy expression of its head is most life-like. Although in our opinion the best of all, this is only one among a number of photographs of various beasts and birds taken by the author himself.

Of the few chapters devoted to mammals, all but one treat of the smaller representatives of the class; but, as if to make up for this, the one exception takes cognisance of the largest of living creatures—to wit, whales. After reading a statement in the introduction to the effect that technical matters were, so far as possible, excluded from the work, we confess to a feeling of surprise at finding nearly three pages of the chapter in question occupied by a technical list of American Cetaceans, many of the names in which are mere synonyms. Apart from this, the chapter is a remarkably interesting one, although it would have been better had some of the illustrations been reduced in size. In view of recent discoveries by the Prince of Monaco, we thought, on first reading the book, that the author was sadly behind the time in his statement that all the markings on Risso's dolphin are normal and not due to conflicts; but this apparent want of revision is fully explained by the date on the title-page. To the same cause may perhaps be attributed the author's relegation of *Zeuglodon* (misspelt, by the way, *Zenglodon*) to a position near the seals, as Prof. Damer's interesting memoir, in which its ancestral cetacean characters are so well brought out, was probably not published in time.

To refer to the other chapters would be to largely exceed our space; and all we can therefore do is to commend the work to the best attention of our readers as an admirable example of what popular natural history should be. Well printed and charmingly and profusely illustrated, it should be welcome alike to young and old, to the professed naturalist and to the non-scientific lover of nature. R. L.

## THE SONGS OF BIRDS.

*Cries and Call-Notes of Wild Birds.* By C. A. Witchell. Pp. xi + 84. (London: Upcott Gill, 1899.)

IN this book the author carefully describes the cries of over a hundred of the commoner species of birds which are to be heard in or near gardens of towns, woodlands, uplands and riverside. No reader who is at all interested in birds can fail to be impressed with the diligence and patience shown in collecting so much detailed information, and with the extraordinary powers of ear which the author seems to possess.

The cries of birds, as Mr. Witchell implies in his preface, are more readily distinguished from one another by differences of timbre than by differences of musical pitch. Owing to the fact that most birds sing at a very high pitch, it is exceedingly difficult for the human ear to recognise the intervals with certainty. Moreover, the vocal apparatus of a bird is such that he naturally produces several sounds within the compass of one tone of our musical scale; and it is for this reason that nearly all attempts to translate a bird's song into our musical notation are failures. Though familiar with the cries of most of the birds Mr. Witchell mentions, we have been quite unable to recognise several of the strains given in his book when played on the piano. Some of the musical illustrations would remind the hearer of the song if he were already familiar with it, but we doubt if they would convey much idea of it to any one else. Descriptions of the cries of birds by means of syllables and words are generally very difficult to interpret. It is easy to make the syllables fit the song when that is known, but the syllables give little idea of a song which is unknown to the reader, because there are no universally recognised rules for their pronunciation. Mr. Witchell has been at great pains, but we do not think really satisfactory results can be obtained in the representation of birds' cries by either of the methods he has employed.

There are few inaccurate statements in the book; but the author is mistaken when he writes concerning the song-notes of the great tit, "It is noteworthy that none of our other titmice have any of these cries." The coal tit sings a song not very unlike the ringing note of the great tit, which is represented by the words "chingsee, chingsee." We have spent many hours listening to grasshopper warblers; but we never yet heard one reel for five minutes without a break, nor for even half that time. And we think the author is unjust to the song of the mistle-thrush when he says, "the listener may be led to imagine that some very musical bantam or other such bird is crowing."

In the present work Mr. Witchell has not set himself to discuss the various problems concerning bird-notes, but he incidentally makes assumptions which seem to require more evidence to justify them. Thus he writes:

"In January and February the songs of the blackbird are much shorter than those heard in May, the young birds of the preceding year requiring some practice before attaining proficiency";

and again he says of the skylark:

"These autumn songs seem to be mostly those of young birds of the year, and consist mainly of repetitions of the call-notes, with the addition of a few more musical sounds."

We should like to have more evidence to show that these are songs of the young birds. It is well known that in February many chaffinches can be heard singing which apparently find it difficult to finish the song correctly. Mr. Witchell makes no mention of this; but surely he would not say that all these chaffinches are young birds.

There is yet another point on which we differ with Mr.

Witchell, and that is with regard to mimicry. Undoubtedly several birds are ready to mimic sounds which they hear about them, but it does not follow that every point of resemblance in the songs of two species is due to mimicry; it is quite as likely to be accidental. For instance, it seems to us fanciful to trace the origin of part of the song of a thrush in the following way:

"The 'kreeow' was given in the deliberate manner of the crow; the 'whillillill' was similar to the note of the wryneck; while the 'tewy' was clearly the call-note of the chiffchaff."

In another place we read:

"The nightingale is sometimes inclined to mimic, and one of its strains, a rapid 'slip slip slip' prolonged, is much like the sound made by the young perching nightingale when the parent is feeding it."

It seems curious that the nightingale should mimic the young birds when they are not yet hatched, for, in spite of the fact that nightingales are heard singing in mid-June, we do not believe that they generally sing after their young are hatched; and Mr. Witchell gives no evidence that the birds he heard were not delayed in their nesting owing to the destruction of their first nest.

Mr. Witchell is well known as a specialist in bird-song, and many of his observations could not be made without a carefully trained ear; so his book cannot fail to be of interest. We are doubtful as to the amount of help it would give to a novice wishing to become familiar with the various cries of birds; but it gives a fuller description of these cries than is generally to be found in ornithological works, and suggests many points which are worth further investigation. H. C. P.

## OUR BOOK SHELF.

*Psychologische Untersuchungen über das Lesen.* By Benno Erdmann and Raymond Dodge. Pp. viii + 360. (Halle, 1898.)

*The Story of the Mind.* By J. M. Baldwin. Pp. 263. (London: George Newnes, Ltd., 1899.)

Painstaking records of psychological experiments are, as a rule, not the most entertaining form of literature. Yet an exception must certainly be allowed in the case of the work of Drs. Erdmann and Dodge, which is no less distinguished by literary charm than by the thoroughness and completeness of the investigations it records. The greater part of this admirable work is devoted to a careful and, in the judgment of the present reviewer, unanswerable refutation of the opinion which since Wernicke has been current among German pathologists, that in normal reading the letters are spelt out separately, one after another. By a series of elaborate experiments the authors seem to establish beyond a doubt that our apprehension of a written text takes place exclusively during the pauses between the movements of the eye along the lines, that six to seven letters can be clearly perceived during each such pause, and finally that a short *word* of not more than four letters can be read off in less time than a single letter. In the later chapters Cattell's well-known experiments on reaction-times for written symbols are submitted to a searching criticism; and it is shown from the absence, under normal conditions, of conflicting optical suggestions or of conscious sensory-motor "feelings of innervation" that no element of "discrimination" or "selection" enters into our ordinary apprehension of the meaning of the symbol. As this means that simple apprehension is *not* "discrimination" of any kind, the result is an important one, and may be commended to the attention of those psychologists who still talk glibly of "discrimination" as the essential feature in perception. Altogether the book is a model of what a psychological monograph should be, clear, well-arranged, and most accurate.

Prof. Baldwin's little book is a valuable addition to the series in which it appears, and should awaken the interest of not a few intelligent general readers outside the little world of psychologists by profession. It is remarkable that he should have been able in so few pages to introduce his readers to almost every side of psychology. The most excellent feature of the book is probably the abundant illustration, from Prof. Baldwin's own researches, of the meaning and nature of psychological experiment. If one were in a fault-finding mood one might, perhaps, complain that the curious attack upon the teaching of language at p. 222 is both exaggerated and irrelevant, and that the concluding chapter on "The Genius and his Environment" is hardly definite enough in its results to justify its being reprinted from the popular magazine in which, no doubt, it has made a previous appearance. A. E. Taylor.

*Sewage Analysis.* By J. Alfred Wanklyn and W. J. Cooper. Pp. xiv + 220. (London: Kegan Paul, Trench, Trübner, and Co., Ltd., 1899.)

*Sewer Design.* By H. N. Ogden, C.E. Pp. viii + 234. (New York: John Wiley and Sons. London: Chapman and Hall, Ltd., 1899.)

The first of these two volumes is described as "a practical treatise of the examination of sewage and effluents from sewage." Many practical hints on the analysis and treatment of sewage are given; and the collection of original papers printed as an appendix contains useful notes and explanations on various analytical processes in chemistry. The object of the book is, however, stated to be to bring about a reformation in the analysis of sewage, and to point the way to its proper disposal. Apparently one of the chief reforms required, according to Mr. Wanklyn, is to induce chemists using the ammonia process of water analysis to express the readings of albuminoid ammonia in terms of parts per million, instead of parts per 100,000 and grains per gallon. But other reforms are urged; and as Mr. Wanklyn claims that "In some respects the opportunities enjoyed by my colleague and myself are absolutely unique," and remarks that "the severance of all relations with the London Chemical Society has operated to our advantage," the volume evidently contains criticisms and conclusions upon which a difference of opinion may be permitted.

Prof. Ogden's volume contains a course of lectures given in the College of Civil Engineering, Cornell University. It shows how the subject of sewer design may be dealt with scientifically, and therefore practically. Much scattered material upon points which have to be considered when preparing the design and making the plans for a system of sewers in a city, has been brought together by the author. Sanitary engineers will find the volume as serviceable for reference as students of sanitary engineering will find it helpful as a text-book.

*The Hygiene of the Mouth, a Guide to the Prevention and Control of Dental Diseases.* By R. Denison Pedley, F.R.C.S. Edin., L.D.S. Eng. Pp. 93. (London: J. P. Segg and Co.)

The importance of taking care of the teeth of children cannot be too strongly emphasised or too widely understood. In this volume the author describes the measures to be adopted for the prevention of dental diseases in adult life, the progress and treatment of dental caries, and some of the consequences of neglect of the teeth. The facts contained in the book should be known to every parent.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### The Magnetic Compass and Nickel Cases.

IT is a common practice amongst instrument makers to put the magnetic compass needle of the pocket compass, or the marching compass used in the army, into an external case of nickel; the case is usually furnished with a lid, after the manner of a hunting watch, and is largely used by travellers.

Recently, while in South Australia, I used such a compass, which was lent to me, for the purpose of steering across a rather large "run." On comparing my position with that indicated by the map, I found that I had drifted considerably to the right of the point laid down; on examining the compass, while slowly shutting the lid, I noticed that as it closed the card of the compass was deflected. I next noticed that the case, which was much discoloured, and at first sight looked like bronze, was made of nickel; this revealed the source of error—when the lid was open, the nickel case, which is magnetic, was unsymmetrical with respect to the magnetic needle, and the needle was attracted by the lid from the true magnetic meridian, and the compass thereby rendered useless for steering purposes, and a source of possible danger, when long distances are traversed.

On talking over the matter with a leading instrument maker, I found that nickel is usually supposed to be a non-magnetic metal, and that nearly every traveller's compass case is made of nickel. It is somewhat remarkable, in an age of so many technical schools, that such ignorance can exist about a metal the properties of which were spoken of by Faraday in 1845 thus: "The magnetic characters of iron, nickel and cobalt are well known" (*Phil. Trans.*, 1846, p. 41). On looking through different price lists of leading firms selling marine compasses, I find that nickel enters into their construction also. In marine compasses the presence of a magnetic metal in the cases must be a source of some danger to the navigator. I would suggest that when selecting a magnetic compass, the magnet needle should be removed, and the case carefully tested for magnetic properties, and that should the case show any signs of magnetism it should be rejected. F. J. JERVIS-SMITH.

Oxford, June 13.

### Historical Note on Recalescence.

IN his recent presidential address to the Iron and Steel Institute, Prof. Sir W. Roberts-Austen stated (NATURE, No. 1541, p. 43): "To Gore, and to Barrett, we owe the investigation of the nature of a fact which had long been well known to smiths, that iron on cooling from a bright red heat suddenly emits a glow."

I do not know what authority Sir W. Roberts-Austen has for this statement, but as this is not the first time it has been made, perhaps I may be allowed to ask if he has any documentary evidence in support of it. So far as I am aware the history of the matter is as follows:—At the meeting of the British Association in Bradford in September 1873, I read a paper entitled "On certain remarkable molecular changes occurring in iron wire at a low red heat"; this was subsequently published in the *Philosophical Magazine* for December 1873. In this paper, the phenomenon, for which I suggested the name *recalescence*, was first described, and was further investigated in other papers of mine, to which I need not here refer. At the time of the discovery it seemed to me highly probable that this remarkable after-glow in cooling iron and steel was likely to have been already noticed, but after considerable search I could find no previous record of it in scientific literature; nor could I, after persistent inquiry, discover a single smith or iron-master who had even casually noticed the effect until I pointed it out to them.

But the most curious thing was that the observation had entirely escaped Dr. Gore's attention; in 1869, Gore discovered that a momentary elongation occurred in a cooling iron wire after it had been heated to bright redness. Dr. Gore, however, did not pursue the matter further, and informed me in May 1872 that he had no intention of doing so (see *Phil. Mag.*, December 1873, p. 473). Writing to me, after the publication of my paper in 1873, in a letter which I happen to have kept, Mr. Gore says:—

"Edgbaston, Birmingham, December 2, 1873. Your new discoveries respecting the molecular changes in iron, described in the *Phil. Mag.* for this month, have greatly pleased me; especially the sudden development of heat attending the elongation during cooling, and the sudden shortening during heating. . . ."[1] And in a letter to me some years later—after the delivery by Prof. Roberts-Austen of a lecture before the British Association in 1889—Dr. Gore naturally expressed his surprise that the discovery or investigation of recalescence should be attributed to him.

It is to M. Osmond more than any one else we owe the series of masterly investigations that has raised the discovery of recalescence into the importance which it now holds in the metallurgy of steel. The value of M. Osmond's work is well known, but I am glad of this opportunity of emphasising it, for M. Osmond's modesty has led him to attribute in his papers, and in his correspondence with me, more value to my own work than it probably deserves. For instance, in a letter addressed to me from Paris on December 13, 1889, M. Osmond writes:—"Vos observations sur la Recalescence sont de celles qui feront époque dans l'histoire de la métallurgie; elles ont été le point de départ de tout ce qu'on a fait pendant ces dernieres années, et pour mon compte, j'ai tant travaillé sur vos traces qu'il me semble vous connaître depuis longtemps. . . ."

I feel sure my friend Sir W. Roberts-Austen will forgive my venturing to correct him in this trifling matter of scientific history. It is quite possible his statement, that recalescence "had long been well known to smiths" prior to 1873, may be derived from his wide metallurgical knowledge, which I do not presume to possess, or it may arise from the common and unintentional blunder of reading our present knowledge into the past. W. F. BARRETT.

Royal College of Science, Dublin, June 2.

IN the Presidential address referred to, I attempted to review the progress made in connection with iron and steel during the past century. I felt that, notwithstanding the very limited space at my disposal for recording the work of individuals, the name of Barrett must find a place, and I greatly regret that my friend considers the reference to him to be infelicitous. As regards the first point raised by him (to take the class of smith's work with which I have most experience), those who have to conduct the very delicate operation of hardening dies for coinage have long been familiar with what is now known, thanks to Prof. Barrett, as "recalescence" in cooling steel. Of course the artificers were ignorant of its true cause, and they usually describe the effect of the sudden glow in steel as being due to "the heat coming from inside the metal." The fact that this industrial knowledge existed, does not in the least diminish the interest of Prof. Barrett's own observation (1873), nor lessen the vital importance of his work in showing that "Gore's phenomenon" (1869) is a reversible one. The relation of the work of Barrett to that of Gore was, moreover, indicated by me nearly ten years ago in the pages of NATURE (November 7, 1889, p. 16) as concisely as I could. In a recent number of NATURE (April 13, 1899, p. 567), a curve obtained by a method of my own is published, and it shows that there are no less than six points at which heat is evolved as iron cools down from 1150° C. to the ordinary temperature. I wish that Prof. Barrett, with his great experimental skill, had hastened the advance of our knowledge by continuing, during the past twenty-five years, investigations which would have led him to the discovery of the several very important points in carburised iron in which, as the

[1] In a note to the Iron and Steel Institute in 1890, and in correspondence with me subsequently, Dr. Gore points out that the discovery of the "sudden shortening during heating" he here attributes to me is more or less implied in his own paper in the *Phil. Mag.* for September 1870, where a molecular change occurring in iron during the process of heating is clearly mentioned. But the only evidence Gore gives of a molecular change during the *heating* of iron is the production of an induced current in a surrounding coil of wire when the iron core reaches a certain temperature; this he correctly attributes to the well-known change in the magnetic state of iron at this temperature. In fact, quoting from his previous paper, Dr. Gore states (the italics are his): "The iron during cooling . . . suddenly elongated by diminution of cohesion . . . a corresponding but reverse phenomenon did *not* occur during the process of *heating* the wire" (*Phil. Mag.*, September 1870, p. 171). In an interesting research on "The changes in length and temperature of iron and steel during recalescence," published in the *Phil. Mag.* for August 1898, M. Svedelius of Upsala supports the historical view I have here taken.

metal cools, the evolution of heat cannot be detected by the unaided eye. I may add that I fully share with M. Osmond, with whom I have so long worked, his appreciation of the value of Prof. Barrett's investigation.

Royal Mint, June 9. W. C. ROBERTS-AUSTEN.

## Harvesting Ants.

IN the spring of 1878 I was much amused with watching the apparent want of common sense displayed by the harvesting ants in storing the little fruits of the plane-tree (*Platanus orientalis*) in one of the avenues at Mentone. It was with much interest, on revisiting the Riviera in May this year, that I observed the same clumsy methods still being adopted by these ants under the plane-trees, not only at Mentone, but also at Hyères and Alassio.

Comparing the fruits to an umbrella in which the ribs are represented by the parachute of long hairs springing from the base or narrower end, while the upper and broader end is frequently surmounted by the remains of the style forming the handle of the umbrella, the ants in bringing the fruits to the nest, hold them pointing out in front, carrying them by the handle. On reaching the entrance, one would naturally suppose they would push them in as one pushes an umbrella into a stand, with the hairs pointing upwards. This would be comparatively easy, as the hairs in question would close round the fruit and offer no obstruction. Instead of doing this, the ants take the trouble to turn round and reverse the fruits, and then attempt to drag the tiny umbrellas in by the handle, the ribs pointing downwards and catching against the sides of the aperture. A large amount of time and energy is wasted by the ants in tugging and struggling with the fruits in order to make them go in, and very often a considerable number of ants are kept waiting about the entrance laden with similar spoil until their turn comes. Occasionally when the aperture is large the fruits go in more easily, but this is exceptional. The considerable "midden" of hairs outside the nests is evidence that the ants remove and reject the hairs after taking all this trouble.

I have never seen the ants carry a fruit into their nests with the hairs pointing upwards, except when I have thrust one well into the aperture in this position, and I have known the ants to reverse the fruits after I have tried to make matters easier for them. The present observations show (1) that after twenty years' experience in the same avenue at Mentone the ants have not learnt such a simple lesson as the proper way to get plane-tree fruits into their nests; (2) that this apparent lack of ingenuity is not restricted to the ants of one particular place, but is shared by the harvesting ants all along the Riviera; (3) that the ants know one method, and one method only.

June. G. H. BRYAN.

## Bessel's Functions.

THE phrases quoted by Prof. Gray furnish additional examples of the laxity of style amongst scientific men, to which "C. G. K." has called attention.

The English language does not readily afford a means of converting the name of a person into the corresponding adjective; and the result is that a slovenly practice has grown up of using the name itself as an adjective. In certain instances, this practice has become sanctioned by usage; and whenever this is the case, the *same* word must be regarded as doing duty for the proper noun and the corresponding adjective. But the practice is not to be commended, and ought always to be avoided if possible.

In my former letter, the word *conception* is a misprint for *corruption*. A. B. BASSET.

Fledborough Hall, Holyport, Berks, June 16.

## Limnology.

As introduced by Prof. Forel, and widely accepted by scientific men in all countries, the term *Limnology* is applied to the science of lakes exactly as *Oceanography* is applied to the science of oceans. It is consequently with some surprise, and even a little shock, that I find a review in the current issue of NATURE headed "Limnology," and dealing with the small organisms of drinking-water. These have been termed *Limnoplankton* by some writers; but treated from the practical point of view their study is surely not Limnology, and from any point of view only a very small part of it. When a scientific term is new and tender, it runs some risk of unintentional abuse which may impair its future usefulness; and I would appeal to scientific writers not to allow *Limnology* to fall into the confusion which now attends *Physiography*. HUGH ROBERT MILL.

THERE is, no doubt, some measure of justice in the remarks of your correspondent. More stress might have been laid on the fact that the book in question, in spite of its title, is much concerned, not only with the numbers, distribution, and seasonal abundance of the organisms in lakes—as stated on p. 147 of the review—but also with statistics regarding the temperature of the water at various depths and seasons, the penetration of light, and other physical phenomena coming under the head of Limnology in the sense required. THE REVIEWER.

June 17.

## "Index Animalium."

WILL you allow me to appeal through your columns for the loan of any of the books in the following list? I wish to see them in order to complete my manuscript from 1758–1800, now rapidly preparing for the press. Parcels may be addressed to me, care of Dr. Henry Woodward, F.R.S., British Museum (Nat. Hist.), London, S.W., and any books lent will be carefully returned in the course of a few days. No other editions are wanted.

### Habits of the Cuckoo.

ONE day last week I was in my garden—a not particularly private country one—when I heard a cuckoo close by, and, standing quite still, I saw the bird alight upon an apple tree not more than four yards from me. The bird did not appear to object to my close proximity, for it uttered its call "cuckoo" twice. Its mate then came and sat in a plum tree only five yards from me, on the opposite side of me; one of them had a caterpillar in its mouth. Then a blackbird came into another tree in a state of great excitement uttering its "pink pink," as I supposed, at the cuckoos; and the question arose in my mind, "Does the cuckoo feed its own young, and was that in the blackbird's nest?" Can any of your readers help me?

WM. H. WILSON.

Gloucester House, Sudbury, Harrow, June 19.

### Economic Entomology.

CAN you tell me where I can get information as to the present condition of economic entomology in this country, more especially as to methods of research usually adopted?

Z.

## MAGNETIC PERTURBATIONS OF THE SPECTRAL LINES.[1]

THE subject which we are about to consider this evening forms a connecting link between two of the most interesting branches of human knowledge—namely, that which treats of magnetism and that which treats of light. Almost as soon as the properties of magnets became known, mere curiosity alone must have prompted philosophers to ascertain if any relation existed between magnetism and "the other forces of nature," as they were generally termed. We are consequently led to expect amongst the records of early experimental investigations some accounts which treat of the action of magnetism on light.

### *Early Experiments.*

When we seek for such accounts, however, we find that they are almost wholly absent from the literature of science, and this arises, I believe, from the great difficulty of the investigation and from the circumstance that only negative results were obtained, rather than that no such inquiry suggested itself or was undertaken. Even in quite recent times this inquiry has been prosecuted, but without success, by physicists who have published no account of their experiments. We may take it, therefore, that the inquiry is in itself an old one, although it is only now that it has been carried to a successful issue.

The earliest recorded attempt to solve this problem with which we are acquainted, is that of a celebrated British physicist whose name must for ever shed lustre on the annals of the Royal Institution—I speak of Michael Faraday. In order to understand the nature of the investigation which Faraday took in hand, and which has led up to the discourse of this evening, it is best to consider briefly some elementary facts concerning magnetism and light.

### *Magnetic Field of Force.*

In the first place, I shall assume that we know in a general way what the peculiarities of a body are which lead us to say that it is magnetised, or a magnet. These are that, when freely suspended, it sets itself in a definite direction over the earth's surface, as illustrated by the compass needle, and that in the space around it there is "magnetic" force exerted on pieces of iron, and, in a smaller degree, on other substances. For this reason, we say that a magnet is surrounded by a magnetic field of force. The field of force is simply the space surrounding the magnet, and it extends to infinity in all directions from the magnet. Near the magnet the force is strong, and far away from it the force is almost insensible; and so we say that the field is strong at certain places near the magnet, and that it is weak at places far away from the magnet. The direction of the force at any point is the direction in which the north pole of another magnet would be urged if placed at that point, and the push which this pole experiences may be taken to represent the intensity or strength of the magnetic field at the point in question. This is represented diagrammatically by these drawings [referring to figures suspended before the audience], which show roughly the nature of the field of force surrounding an ordinary bar magnet, a horse-shoe magnet, and the much more powerful form—the electro-magnet. It will be seen that the space outside the iron is filled with a system of curved lines running from the north pole to the south pole of the iron core. Where the lines are closest together there the magnetic force is strongest, and the direction of a line at any point is the direction of the resultant magnetic force at that point—that is, the direction in which a north pole would be urged if placed at that point.

Faraday always pictured the magnetic field as filled with lines of force in this way, and the importance of the conception can scarcely be over-rated, for it leads us to view the magnetic action as being transmitted continuously through the intervention of some medium filling all space, rather than by the unintelligible process of direct action at a distance. This medium is called the ether; but as to what it is that is actually going on in the ether around a magnet, we cannot definitely say. It may be that there is a flow of ether along the lines of magnetic force, so that there is an out-flow at one end of the magnet and an in-flow at the other, or it may be that the ether is spinning round the lines of force in the magnetic field. For our present purpose, it is not a matter of very much importance what the exact condition of the ether may be in a magnetic field, for if the ether in a magnetic field is either in some peculiar condition of strain or of motion, and if light consists of an undulatory motion propagated through this same ether, then it may be naturally expected that some action should take place when light is propagated through, or radiated in, a magnetic field of force. This is what Faraday suspected, and in order that we may appreciate the problem with which he had to deal, let us place ourselves in his position and ask ourselves the question: "In what manner can we test experimentally if there is any magnetic action on light?"

### *Tests for Magnetic Action on Light.*

In answer to this question, the first thing that occurs to us is to pass a beam of ordinary light through the magnetic field, in some chosen directions, and examine by all the means at our disposal if any action has taken place. When this is done we find that no observable effect is produced. But the scientific investigator does not rest satisfied with one negative result. He varies the conditions of the experiment, and returns to the attack with renewed vigour and hopes. In our first trial we passed a beam of light through the air-filled space around the magnet, and we may vary this experiment either by removing the air altogether, and so causing the beam to traverse a vacuum, or we may replace the air by some dense transparent substance such as glass or water. Under these new conditions, we still fail to detect any influence of the magnetic field on a beam of ordinary light. This negative result might arise from the field of force being too weak to produce an observable effect, or it might be that the effect, if any effect really does exist, may be of such a character that it is impossible to detect it with ordinary light. In common light, the vibrations take place indifferently in all directions around the ray, and follow no law or order as to their type. They

[1] Friday evening discourse delivered at the Royal Institution, May 12, by Thomas Preston, M.A., D.Sc., F.R.S.

possess no permanent relation to any direction around the ray, so that if the magnetic action should happen to be a twisting of the vibrations round the ray, it will be impossible to detect this twist in the case of ordinary light.

*The Faraday Effect.*

As a matter of fact it is a twist of this kind that actually happens, and this is probably what Faraday anticipated. In order to detect it, therefore, it is necessary to employ a beam of light in which the vibrations are restricted to a single plane passing through the ray. Such light is said to be plane polarised, and may be obtained by transmitting common light through a doubly refracting crystal. Faraday found that when a beam of this plane polarised light is passed through the magnetic field, in the direction of the lines of force, a distinct effect takes place, and that the effect is a twisting of the plane of polarisation of the light vibrations as they pass through the magnetic field, or, to be more precise, as the light passes through the matter occupying the field.

This is the Faraday effect. Its magnitude depends on the strength of the field, and upon the nature of the matter through which the light passes in that field. This latter is an important fact that should not be lost sight of in reasoning upon the nature of this effect. The presence of matter in the field appears to be necessary. The effect is not observed in a vacuum, but becomes greater as the field becomes filled with matter of greater density. It is therefore not a direct action of the magnetic field on the light vibrations, but rather an indirect action exerted through the intervention of the matter which occupies the magnetic field.

This action, as we have said, is a rotation of the plane of polarisation of the beam of light, and it arises from the circumstance that in passing through the magnetic field vibrations which take place from right to left do not travel forward with the same velocity as those which take place from left to right. There is no change in the periods of the vibrations, it is essentially a change of velocity of propagation that occurs. If we examine the transmitted light with a spectroscope, we find that the wave-lengths are unaltered, but that the amount of rotation of the plane of polarisation is different for waves of different lengths. The law which governs the effect is that the rotation of the plane of polarisation varies inversely as the square of the wave-length of the light employed.

*Second Form of Experiment (Faraday and Fievez).*

You will have noticed that in the foregoing experiment the source of light was placed quite outside the field of magnetic force, while the beam of light was transmitted through the field for examination. Now we might place the source of light itself in the magnetic field, and then examine if the light emitted by it is in any way affected by the magnetic force. This variation of the experiment suggests itself at once, and was indeed also tried by Faraday—in fact, it formed his last experimental research of 1862, but without success. The same experiment has been tried, no doubt, by many other physicists with the same negative result.

The first recorded success, or at least partial success, was by M. Fievez in 1885. He placed the source of light—a gas flame impregnated with sodium vapour—between the pole-pieces of a powerful electro-magnet. This being done, the light radiated by the flame was passed through the slit of a highly dispersive spectroscope and examined. What M. Fievez observed was that the bright spectral lines became broadened by the action of the magnetic field on the radiating source. His account is, perhaps, somewhat confused, owing to his imperfect apprehension of the true nature of the phenomenon which he observed, but, without doubt, he observed a true magnetic effect on the radiated light—namely, this broadening of the spectral lines—but he did not convince the scientific world that he had made any new discovery, and so the matter fell into neglect until it was revived again in 1897 by the now celebrated work of Dr. P. Zeeman.

*Work of Zeeman, Lorentz, and Larmor.*

The credit which attaches to Dr. Zeeman's work is that he not only, after prolonged effort, succeeded in obtaining this new magnetic effect, but he also convinced the world that the effect was a true one, arising from the action of the magnetic field on the source of light. That Dr. Zeeman was able to do this was due, perhaps, as much to the present advanced state of our theoretical knowledge of this subject as to his own skill and perseverance as an observer; and this is a striking example of the great assistance which well-founded theory affords to experimental investigation. The theory connects the facts already known in reasonable and harmonious sequence, predicts new results, and points out the channels through which they must be sought. Without such scientific theory, this general systematic advance would be impossible, and new results would be stumbled on only by accident.

To see how this applies to our case, we revert to the fact determined by Dr. Zeeman—namely, that when the source of light is placed in a strong magnetic field the spectral lines become broadened (see Fig. 1). As soon as

FIG. 1.—Shows the broadening of the spectral lines by the magnetic field. The upper row shows the lines when the magnet is not excited. The lower row shows the same lines when the magnet is excited. (Reproduced from a photograph, natural size.)

this was announced, Prof. Lorentz, and subsequently Dr. Larmor, examined the question from the theoretical point of view. They analysed the subject mathematically, and came to the conclusion that each spectral line should be not merely broadened, but should be actually split up into three—that is, each line should become three lines, or, as we shall say in future, a triplet. They also arrived at the further most important and interesting conclusion, viz., that the constituent lines of this triplet must be each plane polarised—the central line of the triplet being polarised in one plane, while the side lines are polarised in a perpendicular plane. In fact, the vibrations of the light forming the central line are parallel to the lines of magnetic force, while the vibrations in the side lines are perpendicular to the lines of force. This prediction of tripling and polarisation from theoretical considerations may be regarded as the key to the subsequent advance that has been made in the investigation of this region of physics. In order to understand it, let us place ourselves in Dr. Zeeman's position when he found that the spectral lines became broadened by the magnetic field, and let us be informed that this broadening is in all probability a tripling of the lines accompanied by plane polarisation. The question now is, "How are we to determine if this is the case?"

It is clear that if the broadened line is really a triplet, then the components of this triplet must be so close together that they overlap each other, and so appear to the eye merely as one broad line, as illustrated by the model which is here before you. [Model illustrating the overlapping shown here.] We know that the spectral lines are not infinitely narrow lines, but are really narrow bands of light of finite width, and consequently we are quite prepared to regard the magnetically broadened line as an overlapping triplet, but we cannot remain satisfied until we have proved beyond all doubt that it really is a triplet, and not merely a single broad line. To do this, Dr. Zeeman made use of the second prediction of the theory—namely, that the constituents of the triplet must be plane polarised. If this is so, then the outer edges of the broadened line must be plane polarised, and therefore by introducing a Nicol's prism into the path of the light it must be possible to turn the Nicol so that the plane polarised edges shall be cut off, and the breadth of the line shall be reduced to its normal amount. In fact in this position of the Nicol the outside lines of the triplet are extinguished, and the central component alone remains. This component is, of course, the same in width as the original line, and consequently when the outer members of the triplet are extinguished all the magnetic broadening of the line is removed. When the Nicol is turned through a right angle the central component of the triplet is extinguished, while

FIG. 2.—The lower row shows the lines uninfluenced by the magnetic field. The row next above shows the same lines broadened by the magnetic field. The top double row shows the analysation by a Nicol's prism. (Reproduced natural size.)

the side lines remain, and, if these side lines are sufficiently separated, so that they do not overlap, then, when the central line is removed, a narrow dark space will exist between the side components, which represents the space intervening between the outer members of the triplet, as illustrated by Fig. 2.

But even though we may be able to so increase the strength of the magnetic field that when the central component of the triplet is removed by a Nicol the side lines stand apart with a clearly defined interval between them, yet this in itself does not absolutely satisfy us that the broadened line is a triplet. It might be contended that the broadened line is not really a triplet, but is merely a band of light polarised in one plane along its edges, and in the perpendicular plane along its centre, and that increase of the magnetic field might never separate it into distinct constituents, but merely continue to broaden it. This contention, however, might be disposed of by a careful study of the facts, even though we might not be able to produce a magnetic field strong enough to completely separate the constituent lines of the triplet.

*Actual Triplets Obtained.*

But clearly the thing to be arrived at is to so arrange matters, in fact to so design our electro-magnet and to plan the conditions of our experiment, that the magnetic field acting on the source of light shall be strong enough to completely separate the members of the triplet if such exist. You will understand that this is no easy thing to do when you remember that it was only after repeated efforts and many failures that even a slight broadening of the spectral lines was obtained. Nevertheless, in spite of the great difficulty which besets this investigation, and which arises from our inability to obtain a magnetic field of unlimited strength, yet, with a properly designed magnet and other properly arranged conditions, it is possible to obtain a magnetic field strong enough to completely separate the constituents of the magnetic triplet, and thus to prove that the prediction of theory is verified by the actual facts.

*Other Perturbations, Complex Types.*

But with a magnetic field of great strength the facts as shown by these slides [photographs shown here] turn out to be more complicated and more interesting than the simple theory led us to expect. For while some of the spectral lines are split up into triplets as indicated by

FIG. 3.—The top lines are not subject to the influence of the magnetic field. Underneath the same lines are shown affected by a magnetic field of increasing strength. The line on the right is resolved into a pure triplet, while that on the right appears at first as a quartet, and finally in a very strong field as a sextet (easily seen on the negative). (Reproduced natural size.)

theory, some, on the other hand, become resolved into sextets, or octets, or other complex types (see Fig. 3). Thus when the magnetic field becomes sufficiently intense, we realise to the full all the theoretical predictions and more. The reason of this surplus of realisation over expectation lies in the fact that the theory in its simplest form deals only with the simplest types of motion under the simplest conditions, and the conclusions arrived at are of course of corresponding simplicity. When more complicated types of motion are contemplated, the theory furnishes us with the dynamical explanation of the more complicated types of effect produced by the magnetic field. That tripling pure and simple should occur in the case of every spectral line (as predicted by the simplest form of theory) is not a result which we should expect from a broader consideration of the problem. In fact, if we reflect on the subject, we are forced to the conclusion that deviations from the pure triplet type should be expected, and, as we have seen, such deviations actually do occur. In this respect,

therefore, the experimental investigation which yields more than the simple theory expected is not to be taken as in any way discordant with that theory, but on the contrary to be in harmony with it.

*Theoretical Considerations.*

In order that you may form some idea as to what it is that the theory supposes to be in operation in the production of these phenomena, I have had this elliptic frame constructed [model shown], which I ask you for the present to consider as the orbit described by one of those elements of matter which by their motions set up waves in the ether, and thereby emit what we call light. This white ball, which slides on the elliptic frame, is supposed to represent the element of matter. It is sometimes called an ion, which name is used to imply that the element of matter carries an electric charge inherently associated with it.

Now, under ordinary circumstances this ion revolving in its orbit with very great rapidity will continue to do so peacefully unless external forces come into play to disturb it. When external forces come into action, the orbit ceases in general to be the same as before. The orbit becomes perturbed, and the external forces are termed perturbing forces. But you now ask what is the character of the forces introduced by the magnetic field when the ion is moving through it. In answering this, we are to remember that the ion is supposed to be an element of matter charged with an electric charge—or, if you like, an electric charge possessing inertia. Now, if a charged body moves through a magnetic field, it is an experimental fact that it experiences a force arising from the action of the magnetic field on the moving electric charge. The direction of this force is at right angles both to the direction of motion of the charged body and to the direction of the magnetic force in the field. The effect of this force in our case is to cause the elliptic orbits of the ions to rotate round the lines of magnetic force; or to cause them to have a precessional motion [illustrated by model] instead of staying fixed in space, just as the perturbing forces of the planets in the solar system cause the earth's orbit to have a precessional motion. The angular velocity of this precessional motion is proportional to the strength of the magnetic field, and depends also, as you would expect, on the electric charge and the inertia associated with the ion.

This precessional motion of the orbit, combined with the motion of the ion around the orbit, gives the whole motion of the ion in space, and the result of this combined movement, of these two superposed frequencies—viz. the frequency of revolution of the ion in its orbit, and the frequency of rotation of the orbit around the lines of force—is that, in the case of the light radiated across the lines of force, each period becomes associated with two new periods, or, in other words, each spectral line becomes a triplet. A partial analogue to this, which may to some extent help you to understand the introduction of the two new periods, occurs in the case of sound, although the two phenomena at basis are quite different. The analogue (or quasi-analogue) is this. When two notes of given pitch, that is, of given frequency of vibration, are sounded together, their superposition produces two other notes of frequencies which are respectively the sum and the difference of the frequencies of the two given notes. These are known as the summation and the difference tones of the two given notes. Corresponding to these are the two side lines of the magnetic triplet. The frequency of the vibration in one of these lines is the sum, and the frequency of the other is the difference, of the two frequencies mentioned before—namely, the frequency of the revolution of the ion around its orbit and the frequency of the precessional revolution of the orbit round the lines of force. The centre line of the triplet has the frequency of the original vibration, and this frequency disappears completely when the light is viewed along the lines of force—that is, through axial holes pierced in the pole-pieces. In this direction, too, a further peculiarity arises, for not only does the triplet drop its central member and become a doublet, but each member of this doublet is not plane polarised, as the members of the triplet are. They are each, on the contrary, circularly polarised—that is, the vibration is circular instead of being rectilinear.

This all follows as the expectation of the simple theory which supposes that the ions are free to describe their elliptic orbits undisturbed by any forces other than the magnetic field. But it is only to be expected that other perturbing forces must come into play in the assemblage of ions which build up incandescent matter of the source of light. We know, for example, that the other members of the solar system perturb the earth's motion, so that it deviates from the simple elliptic motion predicted by the simple theory which did not take these perturbing forces into account. Hence, if any such perturbing forces exist, and we should be surprised if they did not exist, the tripling pure and simple of the spectral lines will be departed from, and other types will arise. From the character of these new types we may infer the nature of the perturbations which give rise to them, and hence by the study of these types we obtain a view of what is going on in matter when it is emitting light, which we should not possess if such perturbations did not occur. These deviations from pure tripling are consequently of more importance almost, in regard to our future progress, than the discovery of the tripling itself. To give you some idea of the influence of such perturbations in modifying the triplet form, I may mention that it follows, from simple theoretical considerations, that if the perturbing forces cause the orbit to revolve in its own plane, or cause it to change its ellipticity periodically, then each line of the triplet produced by the magnetic field will be doubled and a sextet will result, and other oscillations of the orbit will give rise to other modifications of the normal triplet type. It is not quite easy to see at once, however, what the perturbing forces are exactly, for we do not know the way in which the ions are associated in matter; but if we regard an ion as a charged element of matter describing an orbit, it will be analogous to a closed circuit, or to a magnetic shell, and will be urged to set in some definite way in the magnetic field. In coming into this position, it may oscillate about the position of equilibrium, and thus introduce an oscillation into the precessional motion of the orbit, which may have the effect of doubling or tripling the constituents of the pure precessional triplet.

Now, experimental investigation shows us that all the spectral lines do not become triplets when viewed across the lines of force in a magnetic field, for some lines show as quartets, or sextets, or octets, or in general as complex triplets derived from the normal triplet by replacing each component by a doublet or a triplet. We conclude, therefore, that the ions which give rise to these complex forms are not perfectly free in their motions through the magnetic field, but are constrained in some way by association with each other in groups, or otherwise, while they move in the magnetic field.

*Law of the Magnetic Effect.*

And now we come to a very important point in this inquiry. According to the simple theory, every spectral line, when viewed across the lines of force, should become a triplet in the magnetic field, and the difference of the vibration frequency between the side lines of the triplet should be the same for all the spectral lines of a given substance. In other words, the precessional frequency should be the same for all the ionic orbits, or the difference of wave-length $\delta\lambda$ between

the lateral components of the magnetic triplet should vary inversely as the square of the wave-length of the spectral line under consideration. Now, when we examine this point by experiment, we find that this simple law is very far from being fulfilled. In fact, a very casual survey of the spectrum of any substance shows that the law does not hold even as a rough approximation; for, while some spectral lines show a considerable resolution in the magnetic field, other lines of nearly the same wave-length, in the same substance, are scarcely affected at all. This deviation is most interesting to those who concern themselves with the ultimate structure of matter, for it shows that the mechanism which produces the spectral lines of any given substance is not of the simplicity postulated in the elementary theory of this magnetic effect.

*Grouping of Spectral Lines.*

Our previous knowledge of the line spectra of different substances might indeed have led us to suspect some such deviation as this from the results predicted by the simple theory. For if we view the line spectrum of a given substance we find that some of the lines are sharp while others are nebulous or diffuse, and that some are long while others are short—in fact, the lines exhibit characteristic differences which lead us to suspect that they are not all produced by the motion of a single unconstrained ion. On closer scrutiny, they are seen to throw themselves into natural groups. For example, in the case of the monad metals sodium, potassium, &c., the spectral lines of each metal form three series of natural pairs, and again, in the case of the diad group, cadmium, zinc, &c., the spectrum of each shows two series of natural triplets, and so on.

Thus, speaking generally, the lines which form the spectrum of a given substance may be arranged in groups which possess similar characteristics as groups. Calling the lines of these groups $A_1$, $B_1$, $C_1$ . . . $A_2$, $B_2$, $C_2$ . . ., $A_3$, $B_3$, $C_3$ . . . we may regard the successive groups as repetitions of the first, so that the A's—that is $A_1$, $A_2$, $A_3$, &c.—are corresponding lines produced probably by the same ion; while the B's—namely, $B_1$, $B_2$, $B_3$, &c.—correspond to one another and are produced by another ion, and so on. This grouping of the spectral lines has been noticed in the case of several substances, and it has been a subject of earnest inquiry amongst spectroscopists for some time past. All such grouping, however, up to the present, has had to depend on the judgment of the observer as to certain similarities in the general character and arrangement of the lines, and similarities which indeed may or may not have any specific relation to the mechanism by which the lines are produced. In fact, such grouping has been effected by guess-work, or by empirical formulæ, and we need not be surprised if it is found that the groups so far obtained are more or less imperfect.

I introduce this grouping of the spectral lines to your notice in order that we may attack the problem of reducing to order the so far apparently lawless magnetic effect. As I have already mentioned, the lines in the spectrum of any given substance are not all resolved into triplets by the magnetic field, but some are resolved into triplets while others become sextets, &c.; and further, the magnitude of this resolution, that is, the interval $\delta\lambda$ between the lateral components, does not appear at first sight to obey any simple law.

*Complex Atoms.*

According to the prediction of the simple theory, the separation $\delta\lambda$ should be proportional to $\lambda^2$, and although this law is not at all obeyed, if we take all the lines of the spectrum as a single group, yet we find that it is obeyed for the different groups if we divide the lines into a series of groups. In other words, the corresponding lines $A_1$, $A_2$, $A_3$, &c., have the same value for the quantity $e/m$,* or, as we may say, they are produced by the motion of the same ion. The other corresponding lines, $B_1$, $B_2$, $B_3$, &c., have another common value for $e/m$, and are produced therefore by a different ion, and so on. We are thus led by this magnetic effect to arrange the lines of a given spectrum into natural groups, and from the nature of the effect we are led to suspect that the corresponding lines of these groups are produced by the same ion, and therefore that the atom of any given substance is really a complex consisting of several different ions, each of which gives rise to certain spectral lines, and these ions are associated to form an atom in some peculiar way which stamps the substance with its own peculiar properties.

In order to illustrate the meaning of this, let us consider the spectrum of some such metal as zinc. The bright lines forming the spectrum of this metal arrange themselves to a large extent in sets of three—that is, they group themselves naturally in triplets. Denoting these triplets in ascending order of refrangibility by $A_1$, $B_1$, $C_1$, $A_2$, $B_2$, $C_2$, &c., we find that the lines $A_1$, $A_2$, &c., show the same magnetic effect in character, and have the same value of $e/m$, so that they form a series obeying the theoretical law deduced by Lorentz and Larmor. In the same way, the lines $B_1$, $B_2$, $B_3$, &c., form another series, which also obeys the theoretical law, and possess a common value for the quantity $e/m$, similarly for the lines $C_1$, $C_2$, $C_3$, &c. The value of $e/m$ for the A series differs from that possessed by the B series, or the C series, and this leads us to infer that the atom of zinc is built up of ions which differ from each other in the value of the quantity $e/m$, that each of these different ions is effective in producing a certain series of lines in the spectrum of the metal. When we examine the spectrum of cadmium, or of magnesium—that is, when we examine the spectra of other metals of the same chemical group—we find that not only are the spectra homologous, not only do the lines group themselves in similar groups, but we find in addition that the corresponding lines of the different spectra are *similarly* affected by the magnetic field. And further, not only is the character of the magnetic effect the same for the corresponding lines of the different metals of the same chemical group, but the actual magnitude of the resolution as measured by the quantity $e/m$ is the same for the corresponding series of lines in the different spectra. This is illustrated in the following table, and leads us to believe, or at least to suspect, that the ion which produces the lines $A_1$, $A_2$, $A_3$, &c., in the spectrum of zinc is

| Magnetic effect | Nonets or complex triplets | Sextets | Triplets |
|---|---|---|---|
| Cadmium ... ... $\lambda=$ | 5086 | 4800 | 4678 |
| Zinc ... ... ... $\lambda=$ | 4811 | 4722 | 4680 |
| Magnesium ... $\lambda=$ | 5184 | 5173 | 5167 |
| Precessional spin ... | $\frac{e}{m}=55$ | $\frac{e}{m}=87$ | $\frac{e}{m}=100$ |

[This table shows the effect for the three lines which form the first natural triplet in the spectrum of cadmium compared with the corresponding lines in the spectra of zinc and magnesium. It will be seen that the corresponding lines in the different spectra suffer the same magnetic effect both in character and magnitude. Thus the corresponding lines 4800, 4722, 5173 are each resolved into sextets, and the rate at which the ionic orbit is caused to precess is the same for each (denoted by $e/m = 87$ in the table). Similarly for the other corresponding lines.]

* The quantity $e$ is the electric charge of the ion, and $m$ is its inertia, and the ratio $e/m$ determines the precessional frequency, or spin, of the ionic orbit round the lines of magnetic force in a given field.

the same as that which produces the corresponding series $A_1$, $A_2$, $A_3$, &c., in cadmium, and the same for the corresponding sets in the other metals of this chemical group. In other words, we are led to suspect that, not only is the atom a complex composed of an association of different ions, but that the atoms of those substances which lie in the same chemical group are perhaps built up from the same kind of ions, or at least from ions which possess the same $e/m$, and that the differences which exist in the materials thus constituted arises more from the manner of association of the ions in the atom than from differences in the fundamental character of the ions which build up the atoms; or it may be, indeed, that all ions are fundamentally the same, and that differences in the value of $e/m$, or in the character of the vibrations emitted by them, or in the spectral lines produced by them, may really arise from the manner in which they are associated together in building up the atom.

This may be an unjustified speculation, but there can be no doubt as to the fascination which inquiry of this kind has always exerted, and must continue to exert, over the human mind. It is the speculation of the ignorant as well as of the philosophic and trained scientific mind, and even though it should never be proved to rest on any substantial basis of fact, it will continue to cast its charm over every investigator of nature.

It is ever the desire of the human mind to see all the phenomena of nature bound by one connecting chain, and the forging of this chain can be realised only gradually and after great labour in the laboratories of science. From time to time, the hope has been entertained that metals may be transmuted, and that one form may be converted into another; and although this hope has been more generally nurtured by avarice and by ignorance rather than by knowledge, yet it is true that we never have had any sufficient reason for totally abandoning that hope, and even though it may never be realised that in practice we shall be able to convert one substance into another, even though the philosopher's stone be for ever beyond our grasp, yet when the recent developments of science, especially in the region of spectrum analysis, are carefully considered, we have, I think, reasonable hope that the time is fast approaching when intimate relations, if not identities, will be seen to exist between forms of matter which have heretofore been considered as quite distinct. Important spectroscopic information pointing in this same direction has been gleaned through a long series of observations by Sir Norman Lockyer on the spectra of the fixed stars, and on the different spectra yielded by the same substance at different temperatures. These observations lend some support to the idea, so long entertained merely as a speculation, that all the various kinds of matter, all the various so-called chemical elements, may be built up in some way of the same fundamental substance; and it is probable that this protyle theory will, in one form or another, continue to haunt the domains of scientific thought, and remain a useful and important factor in our progress, for all time to come.

Even though it may be that a knowledge of the ultimate constitution of matter must for ever remain a sealed book to our inquiries, yet, framed as we are, we must for ever prosecute the extension of our knowledge in every direction; and in pursuing knowledge it frequently happens that vast acquisitions are made through channels which at first seem most unlikely to lead us any further. It has frequently happened that small and obscure effects, obtained after much labour and difficulty, have led to results of the highest importance, while very pronounced and striking effects which have forced themselves on the attention of the observer have proved comparatively barren. It was by a determined effort of this kind, founded on a correct appreciation of the importance of small outstanding differences—so small as to be despised or passed over by all other observers—that Lord Rayleigh discovered a new gas in our atmosphere, added argon to our list of elements, and initiated the attack which led to the brilliant capture by Prof. Ramsay of several new terrestrial substances.

Viewed from this standpoint, I hope I am to some extent justified in occupying your attention this evening with the consideration of the action of magnetism on light, for although the effect produced is small and not easy to observe, yet it is likely to prove an important instrument of research in the study of matter, and it is not inappropriate that a public account of what has been already achieved should be given in this Institution, in which the inquiry was first begun by Faraday, and in which his spirit still lives.

## *THE DOVER MEETING OF THE BRITISH ASSOCIATION.*

THE meeting of the British Association in Dover on September 13 this year promises, on account of its international character, to be a memorable one in the history of the Association. Dover was selected, though it is a smaller town than is usually chosen for these meetings, on account of its nearness to the French coast, in order that an interchange of visits should take place between the British Association and its French counterpart, which meets this year at Boulogne. The French Government has taken a great interest in the arrangements for the meeting, rightly judging that the meeting cannot but promote friendship and good will between the two nations. A good illustration of the truth that science has no nationality will be found in the fact that one of the evening lectures in Dover will be delivered in French by Prof. Chas. Richet, of Paris, on "La vibration Nerveuse." This will take place on Friday, September 15, at 8.30 p.m. It is extremely probable that Prof. Fleming will find some way of imparting an international character to his lecture on the "Centenary of the Electric Current," to be delivered on Monday, September 18.

The preliminary arrangements for the meeting are well in hand. The usual handbook is being prepared under the editorship of Dr. Sebastian Evans, brother of the ex-President of the Association, and will deal with Dover both in its ancient and modern aspect. The historical part of the subject has been undertaken by the Rev. S. P. H. Statham, Chaplain to the Forces, who has recently written a history of the castle, town, and port of Dover. The geology of the district is in the able hands of Prof. Boyd Dawkins; the botany in those of Mr. Sydney Webb. Dr. Parsons undertakes the climate, health and meteorology of Dover; whilst the harbour and cross-Channel traffic is described by Mr. A. T. Walmisley, C.E., the Harbour Board Engineer. This portion of the handbook should be extremely interesting in view of the national harbour which has been undertaken by the Government after more than fifty years' delay, and which will turn Dover into one of our most important naval ports.

For a town of its size Dover possesses an unusually large number of rooms suitable for public meetings, so little difficulty has been experienced in providing for the Sections. The Town Hall, with its annexe, the ancient Maison Dieu, will serve for the President's address and the soirées. The School of Art, in which five of the Sections assemble, adjoins and communicates with the Town Hall. The reception rooms and offices have an ideal *locale* in the buildings and grounds of the Dover College. This institution was founded some thirty

years ago in what remains of the Dover Priory, established about 1130. The magnificent Norman refectory will serve as the reception room and ticket office. The College is only about three minutes' walk from the Priory Station (L.C.D. Railway), and about as far from the Town Hall. Two of the Sections (anthropology and geography) will meet in a part of the town somewhat more remote from the reception room.

There will be no lack of entertainment of a public character. The General Commanding the South Eastern District (Sir Leslie Rundle) will give a garden party at the Castle; the Council, head-master and assistant-masters of Dover College will give another in the College grounds. The Mayor (Sir William Crundall) will give a conversazione, and will also give a reception one afternoon at the Dover Athletic Grounds, when there will be an exhibition and contest of motor cars from all parts of Europe and America.

The smoking concert, which was so successful a feature of the Bristol meeting last year, will be repeated. There will also be a military tattoo by torchlight on the sea front one evening, with music by the massed bands of the garrison.

The visit of the French Association is to take place on Saturday, September 16. The members will arrive early, and, after a light repast at the Lord Warden Hotel, will assemble at the Town Hall, when addresses of welcome will be given. An adjournment will then be made to the various Sections, which will meet on Saturday this year, though that day is generally an "off-day." In many Sections the presidents will reserve their presidential addresses for this occasion, so as to give the French guests a chance of being present. There will be a luncheon afterwards in a marquee in the College grounds. In the afternoon, parties will visit the Castle and other objects of interest in Dover. There may be opportunity for a visit to Canterbury.

On Sunday there will be special services in most of the churches and chapels of Dover, whilst those who care to go further afield can take advantage of the arrangements made by Dean Farrar, of Canterbury, one of the vice-presidents of the Association this year, for there will be special services in the Cathedral, with well-known preachers, and an organ recital in the afternoon. The Canterbury Museum, which owes much to the munificence of its Hon. Curator, Mr. Bennett Goldney, a most useful member of the Dover Local Committee, will be open to members of the Association on Sunday afternoon.

The return visit of the British Association to the French will take place on Thursday, September 21. The details are not finally settled, but there will be a *réunion* with addresses, a luncheon, the unveiling of a plaque to the poet Campbell, who lived at Boulogne for some time. A statue to the French man of science, Duchesne, will also be unveiled. It is intended to start from Boulogne on the five days' excursion through the most interesting towns of Northern France and Belgium. The civic authorities in each town have very cordially responded to the efforts of the French and the Belgian consuls in Dover, and have promised to do all in their power to make the five days' excursion a great success.

Amongst the scientific men from the Continent, the United States and Canada, who have already accepted the invitation of the Local Committee, may be mentioned Profs. Dwelshauvers-Dery, Fittig, Gobert, Julin, Kronecker, Calmette, Chappuis, Barker, Carl Barus, Surgeon-General Billings, Profs. Bovey, Campbell, Scott, Thurston, and Van Rijckevorsel.

From what has been stated, it will be evident that those members of the Association who visit Dover will have no cause to be dissatisfied with the programme before them.

W. H. Pendlebury.

## THE VOLTA CENTENARY EXHIBITION AT COMO.

In this age of electricity it is difficult to realise that only a hundred years have elapsed since the first electric current was produced by chemical means. The birthplace of Alessandro Volta has paid a fitting tribute to the pioneer of electrical science by holding an exhibition in commemoration of the discovery of the pile which bears the name of its inventor.

The Como Exhibition, which was opened on May 20, occupies a tract of land bordering on the Lake of Como, its natural surroundings harmonising well with the artistic arrangement of the buildings and exhibits. One section is devoted to electricity, another to the silk industries of Lombardy, while a small collection of pictures, church vestments, &c., forms a minor feature.

International Congresses of electricians and of telegraphists have been organised at Como. At the latter Congress, which was held on May 31, an inaugural address was given by Di San Giuliano, and a competition between professional telegraphists took place.

In the electric exhibits, applied electricity occupies, as might be expected, the most prominent place. All the machines in the exhibition, including the silk-spinning and weaving machinery, a lift to the top of one of the towers, and a high-pressure pump for supplying the fountains, are worked by electricity, each machine having a separate motor.

The principal source of power is a compound "Brünner" horizontal engine worked by steam supplied from two "Babcock and Wilson" boilers. The 150 horse-power thus supplied is transmitted to a steel shaft, where it can be increased up to 300 horse-power by a motor driven by a three-phase alternating current of 3600 volts, the generating plant for which consists of an engine of 100–150 horse-power by Wolf, of Magdeburg, and an alternator by Gadda and Co., of Milan. The main shaft can be connected with ten dynamos by different makers, varying from 24 to 300 horse-power, and as these cannot all be used simultaneously, a comparison of their efficiency is possible. Subsidiary electric power is supplied by three steam and two gas engines operating on dynamos, by Brioschi and other makers, and a fine series of accumulators is available for reinforcing the supply of power which, even without this help, is available up to 500 horse-power.

A large search-light exhibited by the Italian navy has been placed at Brunate, a station 1500 feet above sea-level, whence its rays can be flashed over Como and the surrounding district to a distance of many miles.

Technical instruction in electricity is well represented, while the purely physical side comprises exhibits of Röntgen ray apparatus, wireless telegraphy, electrostatic apparatus by A. Dall' Eco and other makers, and so forth.

One room in the exhibition buildings is set apart for the "Cimelii di Volta," under which head are comprised Volta's physical apparatus, original manuscripts of his papers, his letters, diplomas, and many of his personal effects. The greater part of these relics are exhibited by the Reale Istituto Lombardo, under whose auspices the collection was formed by public subscription in the years 1861 to 1864; for this collection, one of the rooms belonging to the Society at Milan has been specially set apart. Other relics, chiefly personal, are exhibited by Prof. Alessandro Volta and Prof. Zanino Volta. The University of Pavia exhibits several electroscopes, condensers, and similar electrostatic apparatus; and other exhibits are lent by the Como Museum.

The manuscripts include the following:—

(1) A letter to Volta from the French physicist Nollet, dated September 18, 1767.

(2) A letter from Volta to Prof. Barletti, of Pavia, dated April 18, 1777, containing an anticipation of the electric telegraph. Volta suggests the possibility of connecting Milan and Como with a wire suspended from poles, so that an operator at one end of the line could fire an electric pistol at the other.

(3) A manuscript dated May 14, 1782, dealing with animal electricity.

(4) Volta's paper of March 20, 1800, announcing his discovery of the electric pile to Sir Joseph Banks, President of the Royal Society.

(5) Volta's monograph on the formation of hail, published about 1806.

The apparatus exhibited illustrate Volta's inventions of the electrophorus and the "electric pistol," his application of gas to lamps, combined with an electric gas-lighting apparatus, his invention of the eudiometer, his researches on the capacity of condensers, his condensing electroscope, his investigations on the law of electrostatic force involving the use of the electric balances and the electrometer, his researches on atmospheric electricity, his studies on the expansion of gases, his first forms of voltaic pile, including the columnar pile represented by several examples, also the "crown of cups," and his early experiments on electrolysis. A number of batteries of Leyden jars, electrostatic machines, and other apparatus used by Volta in his experiments, while not referring to any special advancements in science, go far towards giving us an insight into the thoughts and pursuits of a physicist of a century ago, of whom the people of Como feel justly proud. G. H. BRYAN.

## *UNITED STATES GEOLOGICAL SURVEY.*

THE literature of American geology increases at an almost overwhelming rate. We have just received three large volumes containing 2053 pages of letterpress, including Part ii. of the Eighteenth Annual Report of the Survey for 1896-97, being papers chiefly of a theoretical nature; and Part v., the Mineral Resources, in two volumes. We have already called attention in NATURE for May 4 to some of the papers contained in Part ii., of which we received advance copies; these were on "The Triassic Formation of Connecticut," by W. M. Davis, with coloured maps and sections; on the "Geology of the Edwards Plateau and Rio Grande Plain adjacent to Austin and San Antonio, Texas, with reference to the occurrence of underground waters," by R. T. Hill and T. W. Vaughan; and "A Table of the North American Tertiary Horizons, correlated with one another and with those of Western Europe, with annotations," by Mr. William H. Dall.

In addition, this volume contains a report on the "Glaciers of Mount Rainier," by I. C. Russell, with a paper on "The Rocks of Mount Rainier," by G. O. Smith. Associated with the Cascade range in the State of Washington, but of later date and distinct from it both geographically and geologically, are four prominent volcanic mountains, of which one is Mount Rainier, 14,526 feet in height. This mountain is an extinct volcano, but the residual heat of its once molten rocks gives origin to steam-jets, which escape from crevices in the now partially snow-filled craters at the summit. The main mass consists of fragmental andesitic and basaltic materials, with some lava streams; but its outlines have been modified by frost and storms, and deeply sculptured by glaciers. The glaciers are now receding. The scenery around the mountain possesses such great beauty and grandeur that a portion of ground was reserved as a National Park in 1893, and it is now intended to reserve a larger area. Numerous views of the scenery are given.

"The Age of the Franklin White Limestone of Sussex County, New Jersey," is discussed by J. E. Wolff and A. H. Brooks. This limestone occurs in the Pre-Cambrian or Archæan highlands of New Jersey, an area largely occupied by gneisses. These schistose rocks have a nearly constant north-east strike and south-east foliation-dip, with a frequent linear parallel structure which is usually "inclined at a moderate angle to the north-east, lying generally in the plane of dip, and is called 'pitch.'" It is observed that the foliation structure in the limestone is usually parallel to that in the gneiss, and "the pitch structures of the gneiss, white limestone, and associated [magnetite] ore deposits have a general parallelism both in direction and angle." Mr. Wolff regards the pitch-structure as due to primary crystallisation. The authors conclude that the white limestone was deformed, metamorphosed, and partly eroded before the basal member of the Cambrian series was laid down.

"A Geological Sketch of San Clemente Island" is contributed by W. S. T. Smith. This island is the southernmost of a group known as the Channel Islands, which lie off the southern coast of California. It has no permanent human inhabitants except one old man, who has lived there most of the time for the last thirty years. Sheep, cattle and wild goats have been introduced, and there are foxes, lizards and land-shells. The vegetation is limited almost entirely to low shrubbery and herbage. The cactus and "salt-grass" are abundant. The island has a length of nearly twenty-one miles, a maximum width of little over four miles, and an altitude at one point of nearly 2000 feet. It is built up almost entirely of lava flows, with intercalated volcanic breccias and ashes. A detailed account of these is given. Miocene and later sedimentary deposits occupy small areas. The volcanic rocks appear to have been of Miocene age, but older than any of the sedimentary deposits. Attention is drawn to the evidence of faulting which occurred between the close of the Miocene and early Pliocene times, and which has had a marked effect on the physica features of the island. This faulting has continued at intervals ever since.

"The Geology of the Cape Cod District" is described by N. S. Shaler. He discusses the series of geological events which occurred since the beginning of the Cretaceous period in the south-eastern portion of New England. After tilting and the erosion of the Cretaceous and Tertiary beds, various Pleistocene deposits were laid down, and these in turn became somewhat disturbed. The region, in fact, has evidently been one of remarkable instability. A very full and interesting account is given of the structure of the region and of the glacial and post-glacial phenomena, illustrated by numerous views and sections.

"Recent Earth Movement in the Great Lakes Region" is the title of an article by G. K. Gilbert. He points out that although modern movements are of small amount, it is believed that they are of the same kind as the ancient, and that the great changes of the geologic past were effected slowly. His observations now lead to the conclusion that the whole North American lake-region is being lifted on one side or depressed on the other, so that its plane is bodily canted towards the south-south-west, and that the rate of change is such that the two ends of a line 100 miles long and lying in a south-south-west direction are relatively displaced four-tenths of a foot in 100 years. The changes are not directly obvious owing to inequalities of rainfall and evaporation, but the mean height of the lake-surfaces has been affected. With reference to the economic bearings of these changes Mr. Gilbert remarks that the modifications are so slow that they may have small importance in engineering works. He observes, however, that it is a matter of greater moment that cities and towns built on lowlands about Lakes Ontario, Erie, Michigan, and Superior will sooner or later feel the encroachment of the advancing

water, and it is peculiarly unfortunate that Chicago, the largest city on the lakes, stands on a sinking plain that is now but little above the high-water level of Lake Michigan.

The two volumes on mineral resources contain a large amount of valuable information, much of it statistical. The products for 1896 showed only a slight increase in value over those for 1895. There are lengthy reports on iron-ores, on the iron and steel industries of all countries, and on the Witwatersrand banket and other gold-bearing conglomerates, most of which appear to be marine. The evidence given in reference to these auriferous deposits shows that in ancient formations the detrital gold is most likely to be found in marine shore deposits. There are shorter reports on copper, lead and zinc, on aluminium with references to bauxite from Georgia and Alabama, on quicksilver, manganese, nickel, cobalt, antimony, and platinum; 163 ounces of platinum were obtained in the United States, and it is mentioned that a nugget weighing 20 ounces was found in Columbia, South America. Coal and coke are treated very fully, so also are petroleum and natural gas. Building-stones, clays, cement, precious stones, phosphates, mineral paints, and a variety of other substences are dealt with. It is noted that black shale is ground for the pigment known as mineral black. Fuller's earth has been reported from a number of localities. Observations have been made on various limestones considered likely to be useful for lithography, and it is reported that South Dakota promises to furnish suitable stone. The final report is devoted to mineral waters.

## *THE REPORT OF THE INTERNATIONAL AERONAUTICAL SOCIETY.*

THE International Meteorological Conference of Paris, 1896 (NATURE, vol. liv. p. 523) appointed various committees to discuss and report on certain scientific questions. One of these committees was entrusted with all questions connected with the science of aeronautics, such as the scientific use of balloons and kites.

Of this committee, Dr. H. Hergesell of Strassburg was the chairman, and Dr. W. de Fonvielle the secretary.

The committee held a meeting at Strassburg, March 31–April 4, 1898, and the report of this meeting, in two languages—German and French—has just appeared.

The meeting was attended by some twenty-five gentlemen, for the most part original or co-opted members of the committee.

During the interval of eighteen months between the meeting in Paris and that at Strassburg, several concerted balloon ascents had been organised and carried out. The area over which balloons, either manned or simply fitted with registering apparatus, had been sent up, extended from St. Petersburg to Paris, and a fair number of balloons took part on each occasion.

The chief business of the Strassburg meeting was to receive and consider the reports of these concerted experiments, and from the experience gained to arrive, if possible, at improvements in apparatus and arrangements for future work.

Among other matters, the preparation of sufficiently sensitive thermographs, to register sudden alternations of temperature, was especially recommended, and also the use of liquid air for the purpose of testing thermometers liable to exposure to extreme temperatures in unmanned balloons.

An interesting paper by Mr. Rotch on his kite work at Blue Hill Observatory, Massachusetts, was also handed in and included in the report.

Various special reports will be found in the appendices.

## *NOTES.*

A DEPUTATION will wait upon Mr. Balfour to-day to place before him reasons why national support should be given to an Antarctic expedition. It is understood that the Government is favourably inclined to the views of the deputation, and that the intention to make a grant towards the cost of the proposed expedition will be announced.

PROF. E. A. SCHÄFER, F.R.S., has been elected successor to the late Prof. Rutherford in the chair of physiology in the University of Edinburgh. Prof. Schäfer is forty-three years of age, and he has been Jodrell professor of physiology in University College, London, since 1863, when he succeeded Sir J. S. Burdon Sanderson.

THE annual conversazione of the Royal Society took place yesterday evening as we went to press.

SIR W. H. WHITE, K.C.B., F.R.S., will receive the freedom of the borough of Devonport on July 20, and will unveil, at the Technical School, a window descriptive of naval architecture.

DR. W. F. HUME, who during the last eight months has been carrying out a geological and topographical survey of the peninsula of Sinai, under the auspices of the Egyptian Government, has returned to Cairo with his survey party.

DR. CYRUS ADLER contributes to *Science* of June 2 and 9 a detailed account of the proceedings of the second conference on the International Catalogue of Scientific Literature, held at the Royal Society last October. The official Acta of the conference appeared in NATURE of October 27, 1898 (vol. lviii. p. 623).

M. PH. VAN TIEGHEM, Professor at the Museum of Natural History and President of the French Academy of Sciences, has been appointed to the chair of Biology of plants cultivated in France and the Colonies at the National Agronomic Institute, Paris; and M. G. Poirault succeeds the late M. Naudin as Director of the Laboratory for Higher Instruction at the Villa Thuret, Antibes.

PROF. ALFRED GIARD, the president of the section of zoology, anatomy, and physiology of the French Association for the Advancement of Science, has issued a circular in which he points out that as zoological members of the British Association will visit Boulogne, and attend some of the meetings of the French Association, the meeting will afford a good opportunity of discussing questions referring to pisciculture and marine fisheries. Papers dealing with the special zoology of the Channel or of the North Sea are therefore especially invited.

THE International Hydrographic and Biological Congress, which is to discuss the arrangement of periodical researches into the conditions of the North Sea and North Atlantic, was opened at Stockholm on Thursday last. M. Krusenstjerna, Minister of the Interior, delivered a speech, in which he welcomed the delegates in the name of the King of Sweden and Norway. Director-General Akermann (Sweden) was chosen president of the congress.

THE Liverpool School of Tropical Diseases is sending out to the West African coast a special expedition to investigate the causes of malaria and other diseases. The expedition will be headed by Major Ross, the recently-appointed lecturer, and will include Dr. Sunnett, the demonstrator to the Liverpool School. The party will start for Sierra Leone early in August, when the malarial season is at its height, and the conditions are most favourable for research. The expedition hopes to determine, by the methods which Major Ross employed in India,

which are the malaria-bearing species of mosquito in the locality chosen, and then inquire whether it is possible, by filling up the particular puddles in which they breed, to exterminate malaria in a given district.

ON Saturday last, the French naval authorities, acting in conjunction with Mr. Marconi, conducted some successful experiments with wireless telegraphy, between a ship and the shore in the English Channel. The French storeship *Vienne* was used for the purpose. Up to Saturday the distance between the South Foreland and Boulogne, about twenty-eight miles, was the greatest space through which these messages have been transmitted. On Saturday messages were sent between the vessel and the English coast from off Boulogne, and afterwards at intervals, until the vessel was twelve or fourteen miles away from that port. The greatest distance through which the messages were transmitted was forty-two miles. It is stated that Mr. Marconi's method of limiting the area of influence of the waves used was successfully applied. The messages were sent at will either to Wimereux or to the South Foreland, without the other station being able to intercept them.

A MARINE exploring expedition to the mid-Pacific, under the direction of Prof. A. Agassiz, is being arranged by the U.S. Commission of Fish and Fisheries. The expedition will leave San Francisco about the middle of August, and proceed directly to Tahiti, in the Society Islands, which will be made the headquarters while the Paumotu Islands are being explored. In this archipelago, which is about 600 miles long, the *Albatross* will pass six or eight weeks. After returning to the Society Islands, the vessel will go to the Tonga, or Friendly Islands, where a week or ten days will be spent. Thence the vessel will sail for the Fiji-Islands, where a short stay will be made, and thence to the Marshall Islands, visiting a number of the Ellice Islands and Gilbert Islands on the way. Six or seven weeks will be devoted to the exploration of the Marshall Islands. Between the Marshall Islands and the Hawaiian Islands, and between the latter and San Francisco, a distance of over 4000 miles, a line of deep-sea dredgings will be run, deep-sea townets being used while the dredging is going on. The *Albatross* is expected to return to the United States in April next year. Every effort is being made to thoroughly equip the vessel for deep-sea dredging, trawling and sounding; surface and intermediate towing; shore seining; fishing trials with lines and nets; land collecting, and other branches of the work. The newest apparatus for deep-sea and plankton investigations will be supplied. Special appliances are being constructed for use in the very deep water to be found about some of the islands.

A PARAGRAPH on the thermal conductivity of cast iron, as determined by Messrs. E. H. Hall and C. H. Ayres, appeared in NATURE of April 13 (p. 563). The thermal conductivity of the cast iron used was found to be about 0·1490 at 30° C. Mr. I. Thornton Osmond, Dean of the Pennsylvania State College, calls our attention to the fact that this result differs from values obtained under his direction in 1894, and described in the *Physical Review* of that year (vol. ii. No. 3, Nov.-Dec.). For the cast iron used in this investigation, the thermal conductivity from 60° C. to 90° C. or 100° C. was found to be a little over 0·09; and from 150° C. to 200° C. a little over 0·11. Mr. Osmond adds: "Though believing, from theoretical considerations, the conductivity to be a direct function of temperature, these figures were somewhat surprising; and I made preparation to have the work repeated through a greater temperature range and with great care; but this was never carried into effect. The method used was that of Principal Forbes, substituting thermopile and galvanometer for mercury thermometers, thus greatly reducing the cavities in the bar."

WE regret to learn that among other steps taken in reducing the expenditure of the Colony of Jamaica, it has been decided to withdraw the annual contribution towards the Weather Service, which has for the last eighteen years been under the control of Mr. Maxwell Hall, and to substitute a vote of 50*l*. for the collection and tabulation of statistics of rainfall and temperature. The letter from the Colonial Secretary seems to suggest that one reason for the step taken was that the full co-operation on the part of other Colonies and countries, which was necessary to make the scheme a complete one, was not forthcoming. The Service consisted of one first-class station, six stations of the second and third classes, and about two hundred rainfall stations. The vote was a very small one, and the director appears to have done good work, and to have been successful in issuing storm warnings and rainfall forecasts, although the latter could not reach those principally interested. Various useful investigations have been undertaken and published in the Jamaica Weather Reports, or elsewhere.

THE volume of hourly means of the readings obtained from the self-recording instruments at the five observatories under the Meteorological Council, just published for the year 1895, completes the lustrum 1891–1895; an appendix has therefore been added to the usual tables for the year in question, showing the mean values for that period. In addition to these values, hourly and other means of pressure, temperature and rainfall are given for four observatories, for a period of twenty-five years, and of sunshine for fifteen years. These averages afford valuable data for climatological or other more minute investigations. Further, in deference to a recommendation of the international meteorological conference at Paris in 1896, the hourly readings for some elements are given for two stations—Valencia Observatory as a typical Atlantic Coast station, and Kew Observatory as a typical inland station, and it is intended to continue this departure in future volumes.

PROF. ARRHENIUS contributes to the *Revue Générale des Sciences* an interesting account of his investigations into the causes of secular variations of temperature at the earth's surface. It is shown that widespread changes of mean temperature are more likely to be due to variations in the proportion of terrestrial rays absorbed by the atmosphere than to any variation connected with the solar rays, and that the absorption of terrestrial rays is most likely to be affected by changes in the amount of carbonic acid present in the atmosphere. Using Langley's data, it is calculated that if the amount of carbonic acid were diminished by a little more than half, the temperature would be lowered by about 4°·5 C., while an increase to two and a half or three times the present amount would raise the temperature about 8°·5 C., corresponding to the conditions of Glacial and Eocene times respectively. This calculation gives rise to some interesting speculation as to the possibility of such changes having taken place as the result of volcanic or erosive action, and the effect of the artificial consumption of carbon in raising the temperature of the air.

THE *National Geographic Magazine* for May contains a paper by Mr. J. B. Leiberg, entitled "Is climatic aridity impending on the Pacific slope?" The arid non-forested regions of eastern Oregon, and the semi-arid, sub-humid, and humid forest tracts are examined separately, and in each case evidence is found of adverse climatic change taking place in the direction of aridity.

THE parietal eye, with its adjacent organs, of the New Zealand Tuatera (*Sphenodon*) receives attention at the hands of Dr. A. Dendy in the May issue of the *Quart. Journ. Micr. Soc.* This functionless eye, which, although deeply buried in the integument, is better developed in the reptile named than in

any other animal, has hitherto been very generally considered as an unpaired organ. Recent investigations, especially those of the author, point, however, to the conclusion that it was originally dual, like the other sense-organs; and that the parietal eyes were once serially homologous with the functional pair now possessed by vertebrates. In the Tuatera, it is believed that the single parietal eye now developed belongs to the left side, its fellow being represented by an organ of essentially similar structure known as the parietal stalk.

In the June number of *Nature Notes*, Mr. R. Morley calls attention to the great destruction of monkeys on the Gold Coast for the sake of their skins. It is stated that in the five years preceding 1892 the average annual export of their skins reached 175,000, with a value of 30,000*l*. As skins in prime condition are alone purchased, this may be taken to represent a yearly slaughter of 200,000 monkeys, mostly belonging to a species of Guereza (*Colobus vellerosus*). In 1894 the number of skins was 168,405, valued at 41,001*l*.; but in 1896 the number fell to 67,600, with a value of 8,662*l*. This shrinkage tells its own tale; and if effectual steps are not forthwith taken to stop the slaughter, it may be considered as certain that in a few years this very beautiful species will be practically exterminated.

In one respect at least it appears that the Madras University is in advance of kindred institutions at home, as students of history are required to possess some knowledge of ethnology and comparative philology. Surely it is time that the anthropological basis of history and sociology was fully recognised in British universities and colleges. Even the enlightened Madras University has to confess that there are no facilities for practical instruction at the colleges. Fully realising that information merely derived from books or lectures is insufficient for education, Mr. Edgar Thurston, the superintendent of the Madras Government Museum, has, with characteristic energy and enthusiasm, supplied the deficiency so far as he is able, and last year gave a course of demonstrations on practical anthropology at the museum. Mr. Thurston not only instructed the students in the technical methods employed, but demonstrated the forms of skulls and external characteristics of the living, and showed how the statistics so obtained elucidated the problems of the migrations of peoples. The collections of prehistoric archæology in the museum afforded proof of the antiquity of man, and the ethnographical collections illustrated the present condition of various tribes.

The "Struggle between Peoples" is the title of a short paper in the *Bulletins de la Soc. d'Anthropologie*, viii. p. 604, by Félix Regnault, in which he opposes the ordinary view that conquered peoples take refuge in the mountains. It is true the last resistance to invaders is made in the mountains, but that is by the mountaineers, and not by the inhabitants of the plains who have been driven into the mountains. M. Regnault also discusses the effect of a nomad people coming into contact with agriculturists: in some instances, the agriculturists win, and the conquered occupy the less fertile or arid lands; in other cases, the pastoral people conquer the tillers of the soil, but though they temporarily overwhelm them, the latter persist and emerge, and the pastors eventually maintain themselves only in those lands which are favourable to keeping flocks.

A highly interesting and important contribution to the study of immunity is to be found in a paper by Rudolf Emmerich and Oscar Löw, published in a recent number of the *Zeitschrift für Hygiene*. The authors have obtained from cultures of the *B. pyocyaneus* an enzyme which, when inoculated into animals infected with virulent anthrax bacilli, is able to entirely negative the action of the latter. Success has also attended their efforts to immunise animals against anthrax infection. The method of preparing the substance, which they call "pyocyanase-immun-proteidin," is not yet perfect, and the details are promised in a later communication. This enzyme is also able to act deleteriously upon typhoid, diphtheria, and plague bacilli *in vitro*, and, curiously, is much more pronounced in its action under anaërobic conditions. It possesses a remarkable power of retaining its bactericidal properties under exposure to high temperatures. Thus 1½ hours of a temperature of from 85 to 90° C., and exposure for 1½ hours to a temperature of 98°·5, and being steamed for an hour at 98°·5 C., all fail to remove its beneficial characteristics. A prospect is now held out by these investigations of obtaining antitoxic substances in a far less costly and cumbrous manner than is involved in procuring curative serums through the medium of living animals; and perhaps the hope of the authors is not unjustified that, "by means of further improvements in immunising methods, the human and animal organisms may be ultimately protected from every conceivable kind of natural infection . . . it only depends upon obtaining the enzyme of certain pathogenic bacteria in the purest possible condition, and their harmless introduction into the body."

A curious instance of a polymorphous bacterium has been recently given by S. Hashimoto, of Sapporo (Japan), who, working in the Halle Hygienic Institute, has found a microbe which assumes at one time the appearance of small motile rods, at another that of thick, plump cocci hanging together in chains of from ten to twenty individuals, whilst yet more interesting is its assumption of the sarcina form, grouped together in packets consisting of from eight to sixteen individual cells. Every precaution was taken to meet the not unwarranted suspicion that these various appearances were simply due to working with an impure cultivation, but even such a master in technique as Prof. Fraenkl could discern no flaw in the manipulations, and moreover was able to confirm in every particular the interesting discovery of his pupil. The microbe in question was originally obtained from an agar-plate which had been mixed with imperfectly sterilised milk, previously kept for some days in an incubator.

In the June number of the *American Journal of Science* appears a full and detailed memoir of the life and works of the late Prof. O. C. Marsh, with a portrait. Especial interest attaches to the account of his early journeys into Indian territory; and the exposure of the nefarious treatment of the Indians themselves, which he was so largely instrumental in bringing about. The paper concludes with a complete list of Marsh's publications. The writer agrees with the opinion already expressed in this journal, that the time is not yet ripe for forming an adequate estimation of the late Professor's labours.

*Bulletin* No. 61 of the Massachusetts Agricultural College (Hatch Experiment Station) is devoted to an account of the life-history of the asparagus-rust, *Puccinia asparagi*, and of the best modes of treatment of plants infested with it.

In a recent number of Bonnier's *Revue générale de botanique*, M. Guignard records some remarkable observations on the mode of impregnation in *Lilium martagon*. He claims for the two generative nuclei of the pollen-tube the term "antherozoids," to indicate their homology with the corresponding bodies in Gymnosperms and in the higher Cryptogams. Although not provided with cilia, they both elongate and assume a vermiform appearance before entering the embryo-sac, the indications of a spiral form being still evident. The two "antherozoids" both take part in the process of impregnation, the one fusing with the ovum-cell or oosphere, the other with the

secondary nucleus of the embryo-sac, or with one of its constituent polar nuclei, to form the endosperm. There is, therefore, in *Lilium martagon*, according to M. Guignard, a double process of conjugation; but the union of the "antherozoid" with the secondary nucleus of the embryo-sac he regards as a process of "pseudo-fecundation." Similar results have been obtained by Prof. S. Nawaschin, and they have been confirmed by Miss Ethel Sargant in a paper read before the Royal Society on May 4.

THE third part of the series of memoirs, in course of publication by the Cambridge University Press, on the material collected during Dr. Arthur Willey's expedition to the Pacific in search of the eggs of the Pearly Nautilus, has just been issued. Three papers are contained therein, dealing respectively with orthogenetic variation in the shells of Chelonia, by Dr. Hans Gadow; Enteropneusta from the South Pacific, by Dr. Willey; and a collection of Echiurids, by Mr. A. E. Shipley.

AN account of the communications and discussions at the International Congress of Zoologists, which met at Cambridge in August last, was given in NATURE at the time of the meeting (vol. lviii. p. 424). A fine volume of *Proceedings*, edited by Mr. Adam Sedgwick, F.R.S., has now been published by Messrs. C. J. Clay and Sons. The volume contains the papers and addresses read before the congress, with reports of remarks made upon the subjects of these communications, and also during the discussions of specific points of zoological importance. Fifteen coloured plates are appended to the volume to illustrate some of the papers. The nature of the contents can be judged from our summary of the work of the congress, and the editor is to be congratulated upon being able to see the *Proceedings* published nine months after the meeting. Few official reports of international congresses appear with such commendable promptitude.

A DIAZO-BODY is a substance obtained by the interaction of nitrous acid and an amine (such as aniline) under certain conditions of temperature. Perhaps no other reaction in organic chemistry is so important either theoretically or technically, and it is so fundamental that the term "to diazotise" has been coined to express the operation. Diazo-compounds are of the general type $R.N=N.OH$, where R may be any benzene group ($C_6H_5$, and so on), and are distinguished by their great nstability and explosive power, tending to give off nitrogen. By very simple reactions the substance $R.N=N.OH$ may be made to give $R.OH$, $R.Cl$, $RBr$, $RI$, $RH$, $R.NH_2$, $R.NH.NH_2$. In many questions of constitution of benzene ring compounds, the exchange of the diazo-group for the sulphonic group is a necessary step in the argument. The methods hitherto proposed for carrying out this reaction give, in general, very bad yields and involve the production of evil-smelling thio-compounds as intermediary products. In a recent number of the *Berichte*, Dr. Ludwig Gattermann describes a very elegant method, the discovery of which, he states, was due to a happy accident which depends upon the formation of a sulphinic acid directly from the diazo-compound. The diazo solution, preferably as sulphate, is mixed with an excess of sulphuric acid and saturated with sulphur dioxide, and then treated at 0° C. with finely-divided metallic copper, when the sulphinic acid is formed in practically theoretical quantity. The method has been found to be of wide applicability, equally good yields being obtained in the naphthalene series.

THE additions to the Zoological Society's Gardens during the past week include a Hoolock Gibbon (*Hylobates hoolock*, ♂) from Upper Burma, presented by Mr. S. B. Bates; two Blue-bearded Jays (*Cyanocorax cyanopogon*) from Brazil, presented by Mr. Arthur Ussher; a Laughing Kingfisher (*Dacelo gigantea*) from Australia, presented by the Hon. A. Littleton; two Black-bellied Sand-Grouse (*Pterocles arenarius*) from Asia, presented by Mr. G. P. Torrens; twelve Sharp-headed Lizards (*Lacerta dugesi*) from Madeira, presented by Mr. R. H. Archer; two Green Lizards (*Lacerta viridis*), a Tessellated Snake (*Tropidonotus tessellatus*), a Common Snake (*Tropidonotus natrix*), European, presented by the Rev. F. W. Haines; a Northern Mocking-Bird (*Mimus polyglottus*) from North America, presented by Mr. C. Gillett; a Greater Sulphur-crested Cockatoo (*Cacatua galerita*) from Australia, two Spiny-tailed Iguanas (*Ctenosura acanthura*) from Central America, deposited; two Derbian Screamers (*Chauna derbiana*) from Colombia, two Palm Squirrels (*Sciurus palmarum*) from India, a Diamond Python (*Python spilotes*) from Australia, purchased; two Burrhel Wild Sheep (*Ovis burrhel*, ♂ ♀), two Jameson's Gulls (*Larus novae-hollandiae*), bred in the Gardens.

## OUR ASTRONOMICAL COLUMN.

TEMPEL'S COMET 1899 *c* (1873 II.)—M. L. Schulhof has calculated new elements and a continued ephemeris for this comet, using the positions supplied from the observations of Messrs. Perrine and Javelle, made at Lick and Nice respectively. *Astr. Nach.* (Bd. 149, No. 3574).

*Elements.*

T = 1899, September 6·0 Paris Mean Time.

$$\left.\begin{array}{ll} M = & 7^\circ\ 21'\ 50''\cdot5 \\ \pi = & 185\ 36\ 20\cdot0 \\ \Omega = & 120\ 57\ 56\cdot3 \\ i = & 12\ 38\ 52\cdot6 \\ \phi = & 32\ 49\ 38\cdot7 \\ \mu = & 671''\cdot9166 \end{array}\right.$$

($\pi$, $\Omega$, $i$: 1899·0)

During the week the comet travels almost in a direct line between the stars ε and α Bootis. It can only with difficulty be now detected with telescopes of less than three inches aperture.

SPECTRA OF RED STARS (CLASS III. *b*).—In August last, 1898, results of a photographic study of the stars of Secchi's Type IV. (Vogel's III. *b*), made by Mr. Ellerman and Prof. G. E. Hale at the Yerkes Observatory, were discussed at the Harvard Conference (*Astro-Physical Journal*, vol. viii. p. 237, 1898). The photographs were obtained with a spectrograph having only one prism and a long-focus camera (20·0 inches). Since that time the spectrograph has been remodelled and provided with a train of three prisms and a shorter focus camera (10·8 inches), and with this instrument much better photographs have been obtained with shorter exposures. *Bulletin* No. 7 of the Yerkes Observatory contains a short description of these, with a plate showing the spectra of four stars of this class (*Astrophysical*

*Journal*, vol. ix. p. 271, 1899). The examination of the photographs has resulted in the possibility of arranging ten of the stars in a series indicating progressive evolution, and the four given are sufficiently representative to show the changes indicated. These are—

I. 280 Schjellerup = DM 59°·2810 (Magn. 7·8).
II. 273 ,, = 19 Piscium (Magn. 5·5±).
III. 132 ,, = U Hydræ (Magn. 5·5±).
IV. 152 ,, = (Magn. 5·5).

The presence of *bright lines* formerly announced is confirmed by these photographs, and some of these are identical with those observed visually by Prof. Duner at Upsala. Any attempt to establish a connection between these stars and those of other types must include these bright lines, but as yet no star is known intermediate in character between these red stars and other groups. In the absence of a suitable instrument for detecting such bodies at the Yerkes Observatory, advantage has been taken of an offer from Prof. Pickering to photograph suspected objects with the objective prism, and in case this indicates a body of new constitution, the 40-inch refractor and stellar spectrograph will be employed for its detailed examination.

The photographs extend from $\lambda$ 5150 to $\lambda$ 5850, the carbon fluting with maximum about $\lambda$ 563 being specially distinct in the spectra of 19 Piscium and U Hydrae.

*Bulletin* No. 9, in the same number of the *Journal*, p. 273, contains a plate illustrating a later attempt to find some position for these stars of Class III.*b* in the stellar constitutional system. The stars compared are—

I. The Sun (Type II.).
II. $\mu$ Geminorum (Type III.).
III. 132 Schjellerup (Type IV.).

In the region extending from $b_4$ to about $\lambda$ 5300, the spectra of $\mu$ Geminorum (Type III.) and 132 Schjellerup (Type IV.) are almost identical, while in the region slightly less refrangible there are many common lines. Further towards the red the spectra become very dissimilar, the strong flutings of carbon seen in 132 Schjellerup being entirely wanting in $\mu$ Geminorum, although there are a few common features sufficient for comparison. Other photographs in the region $H\beta$ to $H\gamma$ show similar coincidences. These photographs, it is stated, show a decided connection between the two classes of red stars, and the observation of more of them may bring out other links in their relationship.

## REMINISCENCES OF DARWIN—SIR JOSEPH D. HOOKER.

A STATUE of Charles Darwin by Mr. Hope Pinker, presented to the University of Oxford by Prof. Poulton, Hope Professor of Zoology, was unveiled at the University Museum on the 14th inst., and Sir Joseph D. Hooker delivered the following address, which we reprint from the *Times*, upon the occasion :—

The Vice-Chancellor of your University has done me the honour of asking me to address you on the occasion of the installation of the statue of the great naturalist which now adorns your museum, and has expressed his opinion that a few personal reminiscences would be more acceptable to you from me than an *éloge* of Mr. Darwin's researches and discoveries, of which latter indeed an excellent reasoned *résumé* is well known to you as the work of your Hope professor of zoology. In accepting the task of giving personal reminiscences, I am reminded of the fact that narrators of an advanced age are not only proverbially oblivious, but are too often the victims of self-deception in respect of what they think they remember, to which must be added that where a dual personification is attempted the narrator is apt to assume the more prominent position. I have thus many snares to avoid, and must hope for a lenient judgment on what follows.

### EARLY FRIENDSHIP WITH DARWIN.

The fact of our having commenced our scientific careers under very similar conditions favoured the rapid growth of a bond of friendship between Mr. Darwin and myself. We both of us, immediately after leaving our respective Universities, commenced active life as naturalists under the flag of the Royal Navy ; he as a volunteer eight years before me, who was an official. We both sailed round the world, collecting and observing often in the same regions, many of them at that time seldom visited and since made accessible to science by his researches—the Cape Verde Islands, St. Helena, Rio, the Cape of Good Hope, the Falkland Islands, Tierra del Fuego, Tasmania, and New Zealand. On returning to England we both enjoyed the rare advantage of the counsel and encouragement of one of the greatest leaders in science of the time—Mr., afterwards Sir Charles, Lyell. It was through the father of Sir C. Lyell, the translator of the "Vita Nuova" of Dante, and a friend of my father, that I first heard of Mr. Darwin. The "Journal of Researches into the Natural History and Geology of the Countries visited during the Voyage of the *Beagle*" was then passing through the press, and the proof sheets were being submitted to Sir C. Lyell for his information and criticisms. These were passed on to Sir Charles's father, himself a naturalist, who was permitted to lend them to me for perusal, because I was then preparing to accompany Sir James Ross as a naturalist on the Antarctic expedition (1839–43). At that particular time I was engaged upon engrossing hospital duties, and I slept with the proofs under my pillow that I might at once, on awaking, devour their contents. They impressed me profoundly, I may say despairingly, with the genius of the writer, the variety of his acquirements, the keenness of his powers of observation, and the lucidity of his descriptions. To follow in his footsteps, at however great a distance, seemed to be a hopeless aspiration ; nevertheless they quickened my enthusiasm in the desire to travel and observe. A copy of the complete work was a parting gift from Mr. Lyell on the eve of my leaving England, and no more instructive and inspiriting work occupied the bookshelf of my narrow quarters throughout the voyage. In the interval I had been introduced to Mr. Darwin, on a casual meeting in Trafalgar-square by a brother officer who had accompanied him in the *Beagle* to Rio, when I was impressed by his animated expression, heavy beetle brow, mellow voice, and delightfully frank and cordial greeting to his former shipmate. Shortly after the arrival in England of the Antarctic expedition (in 1843) I received from Mr. Darwin a long letter, warmly congratulating me on my return to my family and friends, directing my attention to the importance of correlating the flora of Fuegia with those of the Cordillera and of Europe, and inviting me to study and publish the botanical collections which he had made in the Galapagos Islands, Patagonia, and Fuegia.

### VISITS TO DARWIN AT DOWN.

This led to an interchange of views on the subject of geographical distribution, followed by an invitation to visit him at what he used to call his inaccessible home at Down, which was then eight or ten miles distant from the nearest railroad station. This I joyfully accepted ; and then commenced that friendship which ripened rapidly into feelings of esteem and reverence for his life, works, and character that were never clouded for one instant during the forty subsequent years of our joint lives. In the admirable biography of his father by my friend, Prof. Frank Darwin, are recorded the subjects, especially botanical and geographical, which were for many years the subjects of conversation and correspondence between us. During the many visits to Down which followed, he laid before me without reserve, not only his vast stores of knowledge, but his mature and immature speculations and theories, describing how they originated, and dwelling on their influence on the progress of his researches. Among these, so long ago as 1844, was his sketch of "The Origin of Species," which I was the first to see of the few friends to whom he ever showed it. At that very early period of my own studies I failed to grasp its full significance, *à propos* of which I may mention that I have been reproached for this by friends who have wondered, not only that I did not assimilate it at once, but that I did not apply it to my earliest essays on the distribution of plants. My friends overlooked the fact that the communication was a confidential one, of a hypothesis which its author hoped to establish as a tenable theory by an accumulation of facts in support of it, which he was engaged in collecting with a view to future publication. On the occasions of many other visits it was Mr. Darwin's practice to ask me, shortly after breakfast, to retire with him to his study for twenty minutes or so, when he brought out a long list of questions to put to me on the botanical subjects then engaging his attention. These questions were sometimes answered offhand, others required consideration, and others a protracted research in the Herbarium or in the gardens at Kew. The answers were written on slips of paper, which were deposited in bags or pockets that hung against the wall within

reach of his arm, each of them a receptacle devoted to a special object of inquiry. To me this operation of "pumping," as he called it, was most instructive. I could not but feel that any information that I could give him was comparatively trivial, while what I carried away was often as much as I could stagger under. As his health fluctuated or declined, and especially during his sharper attacks of illness, these interviews became intermittent, and on such occasions he would ask me to bring my own work with me to Down, where I pursued my studies free from the distractions of Kew, and with the advantages of his counsel and aid whenever desired. These morning interviews were followed by his taking a complete rest, for they always exhausted him, often producing a buzzing noise in the head, and sometimes what he called "stars in the eyes," the latter too often the prelude of an attack of violent eczema in the head, during which he was hardly recognisable. These attacks were followed by a period of what with him was the nearest approach to health, and always to activity. Shortly before lunch I used to hear his mellow voice under my window, summoning me to walk with him, first to inspect the experiments in his little plant-houses, and then to take a precise number of rounds of the "sand-walk," which he trudged with quick step, staff in hand, wearing a broad-brimmed straw hat and light shooting coat in summer, and a felt hat and warm cape in winter. This walk was repeated in the afternoon; on both these occasions his conversation was delightful, animated when he was well enough, never depressing however ill he might be. It turned naturally on the scenes we had witnessed in far-away regions and anecdotes of our seafaring lives, and on the discoveries in science, then, as now, hurrying onwards and treading on one another's heels in their haste for recognition. In the evening we had books and music, of which latter Mr. Darwin was, during the first few years of our friendship, almost passionately fond. I well remember now, at the 1847 meeting of the British Association in this city, his asking me to accompany him to hear the organ at New College Chapel, and, on coming away, saying to me, "Hooker, I felt it up and down my back;" and I find in the "Life and Letters" that when a student at Cambridge, after hearing a beautiful anthem, he made use of a similar expression to a friend who had accompanied him. It is a curious fact that music should have had in after life no charm for him—that "it set him thinking too energetically at what he had been at work on instead of giving him pleasure."

### An Estimate of Darwin's Character.

If I were asked what traits in Mr. Darwin's character appeared to me most remarkable during the many exercises of his intellect that I was privileged to bear witness to, they would be, first, his self-control and indomitable perseverance under bodily suffering, then his ready grasp of difficult problems, and, lastly, the power of turning to account the waste observations, failures, and even the blunders of his predecessors in whatever subject of inquiry. It was this power of utilising the vain efforts of others which in my friend Sir James Paget's opinion afforded the best evidence of Darwin's genius. Like so many men who have been great discoverers, or whose works or writings are proofs of their having intellects indicating great originality, he was wont to attribute his success to industry rather than ability. "It is dogged that does it" was an expression he often made use of. In his autobiography he says of himself, "My industry has been nearly as great as it could have been in the observation and collection of facts"; and, again, "of the complex and diversified mental qualities and conditions which determined my success as a man of science, I regard as the most important the love of science—unbounded patience in long reflecting over many subjects—industry in observing facts, and a fair share of invention, as well as of common sense." In this introspection he has, if my judgment is correct, greatly undervalued "invention"; that is originality or that outcome of the exercise of the imagination which is so conspicuous in every experiment he made or controlled, and in the genesis of every new fact or idea that he first brought to light. Referring to his disregard when possible of his bodily sufferings, I remember his once saying to me that his sleepless nights had their advantages, for they enabled him to forget his hours of misery when recording the movement of his beloved plants from dark to dawn and daybreak. For those other qualities of head and heart that endeared Mr. Darwin to his friends I must refer you to the "Life and Letters." There is only one upon which I would comment, it is that passage of his autobiography where he says, "I have no great quickness of apprehension or wit." Possibly the "of" and "or" are here transposed; whether or no, my impression of his conversation has left the opposite as characteristic of him. It is, at any rate, inconsistent with the fact that in arguing he was ever ready with repartee, as I many times experienced to my discomfiture, though never to my displeasure; it was a physic so thoughtfully and kindly exhibited. And I may conclude these fragmentary records with an anecdote which goes, I think, to support my view, and which I give, if not verbally correctly, as nearly as my memory of so ancient an episode permits. I was describing to him the reception at the Linnean Society, where he was unable to be present, of his now famous account of "The two forms or dimorphic condition of Primula," for which he took the common primrose as an illustration. On that occasion an enthusiastic admirer of its author got up, and in concluding his *éloge* likened British botanists who had overlooked so conspicuous and beautiful a contrivance to effect cross-fertilisation to Wordsworth's "Peter Bell," to whom

> "A primrose on the river's brim
> A yellow primrose was to him,
> And it was nothing more."

When I told Mr. Darwin of this he roared with laughter, and, slapping his side with his hand, a rather common trick with him when excited, he said, "I would rather be the man who thought of that on the spur of the moment than have written the paper that suggested it."

## "*AMERIND*"—*A SUGGESTED DESIGNATION FOR AMERICAN ABORIGINES.*

A PART of the *Proceedings* of the Anthropological Society of Washington, at a meeting on May 23, seem destined to produce permanent influence on ethnologic nomenclature; this part of the proceedings taking the form of a symposium on the name of the native American tribes. The discussion was opened by Colonel F. F. Hilder, of the Bureau of American Ethnology, with a critical account of the origin of the misnomer "Indian," applied by Columbus to the American aborigines; he was followed by Major J. W. Powell, who advocated the substitution of the name *Amerind*, recently suggested in a conference with lexicographers. A communication by Dr. O. T. Mason followed, in which the various schemes of ethnologic classification and nomenclature were summarised and discussed. Contributions to the symposium were made also by Dr. Albert S. Gatschet, Dr. Thomas Wilson, and Miss Alice C. Fletcher. At the close of the discussion the contributions were summarised by President McGee as follows:—

(1) There is no satisfactory denotive term in use to designate the native American tribes. Most biologists and many ethnologists employ the term "American"; but this term is inappropriate, in that it connotes, and is commonly used for, the present predominantly Caucasian population. The term "Indian" is used in popular speech and writing, and to a slight extent in ethnologic literature; but it is seriously objectionable in that it perpetuates an error, and for the further reason that it connotes, and so confuses, distinct peoples. Various descriptive or connotive terms are also in use, such as "North American Savages," "Red Men," &c.; but these designations are often misleading, and never adapted to convenient employment in a denotive way.

(2) In most cases, the classifications on which current nomenclature are based, and many terms depending on them for definition, are obsolete; and the retention of the unsuitable nomenclature of the past tends to perpetuate misleading classifications.

(3) While the name "Indian" is firmly fixed in American literature and speech, and must long retain its current meaning (at least as a synonym), the need of scientific students for a definite designation is such that any suitable term acceptable to ethnologists may be expected to come into use with considerable rapidity. In this, as in other respects, the body of working specialists form the court of last appeal; and it cannot be doubted that their decision will eventually be adopted by thinkers along other lines.

(4) As the most active students of the native American tribes, it would seem to be incumbent on American ethnologists to propose a general designation for these tribes.

(5) In view of these and other considerations, the name *Amerind* is commended to the consideration of American and foreign students of tribes and peoples. The term is an arbitrary compound of the leading syllables of the frequently-used phrase "American Indian"; it thus carries a connotive or associative element which will serve explicative and mnemonic function in early use, yet must tend to disappear as the name becomes denotive through habitual use.

(6) The proposed term carries no implication of classific relation, raises no mooted question concerning the origin or distribution of races, and perpetuates no obsolete idea; so far as the facts and theories of ethnology are concerned, it is purely denotive.

(7) The proposed term is sufficiently brief and euphonious for all practical purposes, not only in the English, but in the prevailing languages of continental Europe; and it may readily be pluralised in these languages, in accordance with their respective rules, without losing its distinctive sematic character. Moreover, it lends itself readily to adjectival termination in two forms (a desideratum in widely-used ethnologic terms, as experience has shown), viz. *Amerindian* and *Amerindic*, and is susceptible, also, of adverbial termination, while it can readily be used in the requisite actional form, *Amerindise*, or in relational form, such as *post-Amerindian*, &c.; the affixes being, of course, modifiable according to the rules of the different languages in which the term may be used.

(8) The term is proposed as a designation for all of the aboriginal tribes of the American continent and adjacent islands, including the Eskimo.

The working ethnologists in the Society were practically unanimous in approving the term for tentative adoption, and for commendation to fellow-students in this and other countries.

## MAGNETIC OBSERVATIONS AT MAURITIUS.[1]

DR. MELDRUM'S name is inseparably connected with the fortunes of the Royal Alfred Observatory. The value of his researches in meteorology, especially in cyclonic movements of the atmosphere, has been repeatedly acknowledged. The simple rules that he has enunciated for the handling of ships during hurricanes in the Southern Seas are based upon rigorous scientific grounds, and though it may be true that no completely satisfactory rule is possible for determining more than the approximate position of the central vortex of a cyclone by any observations at a single station, yet in a majority of cases the mariner who trusts strictly to the instructions provided will find himself in a position of safety. The recent publication of the Mauritius magnetic reductions by Mr. Claxton, the present director of the Royal Alfred Observatory, shows that Dr. Meldrum devoted himself not less energetically to the study of the absolute determinations of the magnetic elements of his station. We may never arrive at the happy condition foreshadowed by Gauss, when trustworthy and complete observations from all parts of the earth shall be obtained, but the possession of a continuous record from a distant outlying station has a value peculiarly its own, and may act as a stimulus to the establishment of other observatories in localities where they are most needed to provide material for the discussion of the amount of change in the magnetic potential of the earth, of which the simultaneous magnetic disturbances afford evidence.

Mr. Claxton, with a loyalty which we recognise and appreciate, is content to stand aside and play the part of editor to his predecessor's work. But the arrangement is not very satisfactory, giving rise as it does to two introductions, one by the editor and one by Dr. Meldrum. If the information derivable from these two sources had been carefully welded into one consecutive history, the description of the tables could have been followed more easily, and the processes employed in the reductions have been more readily apprehended.

The general arrangement does not call for any special remark. All who have been engaged in similar work know the amount of labour involved, and the care that has to be exercised. We notice what we think is a very praiseworthy feature, a determined effort to maintain a uniformity of sensitiveness on the photographic record. A difference of one m.m. in the scale reading is intended to represent a scale value of ·0005 millimetre-milligramme. This is a convenient value, sufficiently sensitive to exhibit changes for ordinary magnetic disturbances, but yet not so sensitive as to send the spot of light off the paper even in a violent magnetic storm. But Dr. Meldrum reports that it is impossible in spite of every precaution to keep this value of the coefficient constant. The length of time elapsed between the cleaning of the knife edge and the agate plane, the temperature, the change of level of the magnet due to secular decrease in the value of the vertical force, all operate as disturbing causes, necessitating continual examination and readjustment. Tables of the scale coefficient employed are given. The horizontal force magnet shows as usual the larger variation.

Mr. Claxton gives in a tabular form the more trustworthy determinations of declination and dip that have been made on the island of Mauritius since 1750. Lacaille gave 52° 55′ for inclination in 1761, and in 1896 this angle had increased to 54° 32′. The earliest determination of declination gave 16° 30′ W. in 1753, it now reads 9° 49′; but the director points out, which indeed is sufficiently obvious, that there are large discrepancies among the observations arising probably from the use of indifferent instruments and the effect of local magnetic attraction, varying at the different spots at which the several determinations have been made. For these reasons, no attempt has been made to discuss the secular variation of any of the magnetic elements.

[1] "Mauritius Magnetical Reductions." Edited by T. F. Claxton, F.R.A.S. Being a discussion of the results obtained from the self-recording magnetometers from 1875 to 1890, under the direction of C. Meldrum, M.A., LL.D., F.R.S.

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—In a congregation held on June 13 the Curators of the University Chest were authorised to expend a sum not exceeding 10,000*l.* in the erection of a pathological laboratory on ground adjoining the University Museum, and also to pay the sum of 250*l.* a year for five years for the equipment and maintenance of this laboratory from the date at which it shall be brought into use. An anonymous donor, a member of the University, has already offered the sum of 5000*l.* towards the erection of this laboratory, provided that it be commenced before January 1, 1901.

The above decrees were passed by Convocation on June 20, when also the twenty-fourth annual report of the visitors of the University Observatory was presented. In consequence of this report, the Curators of the University Chest will be asked to expend a sum not exceeding 500*l.* in the reconstruction of the western dome of the observatory.

It is proposed to adapt the upper floor of the Ashmolean Museum for the purposes of instruction in geography.

CAMBRIDGE.—At St. John's College the following awards in Natural Science were made on June 19:—

Foundation Scholarships continued or increased: Rudge, Yapp, Howard, Brown, Harnett, Lewton-Brain, O. May, Adams, Fletcher, Harding, Browning, Gregory, Wakely, Williams, Walker.

Exhibitions: Wyeth, Ticehurst, J. H. Field, King, Paton.

Hutchinson Studentship for research (botany and zoology): G. S. West.

Research Prize (physics): Vincent.

Herschel Prize (astronomy): Eckhardt.

A CORRESPONDENT informs us that Mr. G. Birtwistle, who was bracketed Senior Wrangler this year with Mr. R. P. Paranjpye, has not only had much success in mathematics during his career, but has distinguished himself in other subjects. When at Owens College he devoted himself chiefly to chemistry, and in 1896 graduated B.Sc. with first-class honours in chemistry, obtaining also a Le Blanc medal and University scholarship. With regard to Mr. Paranjpye, the Allahabad correspondent of the *Times* states that he is a Maratha Brahmin, born twenty-three years ago in the village of Murdi, in the Ratnagiri district. First in the first division has been his invariable record since in 1891, at the age of fifteen, he headed the list at the matriculation examination for the whole of the Bombay Presidency. During his three years at Fergusson College he passed first in the first class at every examination. Fergusson College is an institution manned entirely by native professors, and Mr. Paranjpye, before going to England, pledged twenty years of his life to service in the college, where he will draw a salary not exceeding Rs.70 a month.

THE quinquennial meeting and international congress convened by the International Council of Women will be held in London on June 26–July 5. A number of subjects in the progress of which women take active part will be discussed in the various sections of the congress. In the educational section the life and training of the child, primary education, universities, modern educational experiments, technical education, women as educators, co-education, training of teachers, and examinations, will be brought forward. In the professional section, among the subjects of papers and discussions are: professions open to women, and the work of women in physical and biological sciences. Other subjects to be discussed are farming in its various branches as an occupation for women, and the training of women in agriculture, horticulture, and other trades and professions.

IN an address delivered at the Leys School, Cambridge, on Friday last, Mr. A. J. Balfour referred to the educational values of science and literature. In the course of his remarks he said: "I cannot really conceive that any man, however enamoured of scientific method, should for a moment undervalue that insight into human nature and the interests which have always stirred human nature, and the manner in which those interests have been transformed by men of genius from time to time in the imaginative crucible of literature—I cannot imagine that such a training should be undervalued even by the most rigid advocate of scientific method. On the other hand, is it credible that in these days there should any man be found who should undervalue that curiosity about the world in which we live which science cannot indeed satisfy, but towards the satisfaction of which, after all, science is the only minister?" The claims of science are here given fair recognition, and men of science do not usually ask for more than this. Their complaint is that science is too often regarded as the Cinderella among school and university subjects; and it is only of late years that any noteworthy improvements have taken place in her position.

AN interesting account of the "Mosque of the Olive Tree" (Jama-Ez-Zituna) at Tunis, one of the three great centres of Mahomedan learning in North Africa, the others being El Azhar in Cairo and the Great Mosque at Fez, in Morocco, is given in a recent report by Sir Harry Johnston. Over 400 students are usually taught at this University, while there are about 100 professors. The lectures begin at sunrise and continue until sunset, fifteen different lectures usually going on at the same time. Each professor sits cross-legged, with his back against one of the many columns of the mosque, his students grouped about him. Until recently, there was but little method in the instruction; each professor rambled on in his discourse, ranging over any topic on which he cared to impart information, and the students listened or not as they chose. To encourage a more practical education, the State offered the students exemption from military service and from certain taxes if they passed an elementary outside examination; but only four of sixty-six recently succeeded in doing this. In future, it is intended to impress on the management of the mosque that each professor should keep to one subject; that the student should be obliged to take notes, and pass periodical examinations. External lectures on scientific subjects and on matters of present-day interest have also been established, and about 100 students from the mosque now attend these.

## *SOCIETIES AND ACADEMIES.*

### LONDON.

**Royal Society**, April 27.—"On the Presence of Oxygen in the Atmospheres of certain Fixed Stars." By David Gill, C.B., F.R.S., &c., Her Majesty's Astronomer at the Cape of Good Hope.

The observations described confirm the conclusions arrived at by Mr. F. McClean and Sir Norman Lockyer as to the existence of oxygen lines in the spectrum of $\beta$ Crucis. From measures of photographs of the spectrum of this star, it is concluded that the whole of the known helium lines within the measured range of spectrum are unquestionably present, as also are all known oxygen lines stronger than intensity 4.

"There remains not the slightest doubt that all the stronger oxygen lines are present in the spectrum of $\beta$ Crucis, at least between $\lambda$ 4250 and 4575, and this fact requires no further aboratory experiments for its establishment. It is almost equally certain that there is no trace of true nitrogen lines in this spectrum. . . . Besides hydrogen, helium and oxygen, the spectrum of $\beta$ Crucis shows the probable presence of carbon (4267·2) and magnesium (4481·17). . . . The spectra of $\beta$ Crucis, $\beta$ and $\epsilon$ Canis Majoris, and probably $\beta$ Centauri are all practically identical."

**Linnean Society**, June 1.—Dr. A. Günther, F.R.S., President, in the chair.—Mr. W. B. Hemsley, F.R.S., exhibited a selection of high-level plants from the collections formerly made by Sir Joseph Hooker, Dr. Thomson, General Sir R. Strachey, and more recently by Captain Welby, Mr. and Mrs. Littledale, and Mr. Arnold Pike in Northern India, Tibet, and Mongolia, many of them from altitudes of 18,000 to 19,200 feet. A selection was also shown from the collections made in the Andes by Sir Martin Conway, Mr. Fitzgerald, Mr. Gosse, and Mr. Whymper, at various altitudes up to 18,500 feet. The principal points referred to were the small size of many of the plants, the protective woolly covering of others, and the general preponderance of the natural order *Compositae*.—On behalf of Mr. Rupert Vallentin, Mr. J. E. Harting exhibited lantern slides of the so-called "Sea-Elephant" (*Macrorhinus elephantinus*), prepared from photographs taken in February last by Mr. Vallentin in the Falkland Islands. After briefly tracing the distribution of this huge seal on various Antarctic and subtropical islands, Mr. Vallentin's notes on a specimen killed in Stanley Harbour were read. This specimen measured 18 feet 11 inches from the end of the trunk to a straight line between the two hinder extremities; the trunk, produced by the inflation of a loose tubular sac of skin above the nostrils, is present only in the male, and measures, when fully extended, twelve inches from the gape. No fresh facts were made known concerning the nature of the food of this animal, described by some writers as herbivorous like the manatee, by others as feeding on mollusca and crustacea like the walrus. In this case the stomach was empty, with the exception of a large number of Nematode worms, specimens of which were exhibited.—Mr. Harting also exhibited and made remarks on some living specimens of the Bank vole (*Microtus glareolus*), recently obtained by Mr. Robert Drane on Skomer Island, Pembrokeshire.—Mr A. W. Bennett exhibited and described a remarkable Alga from Scotland (*Lyngbya* sp. ?) possessing a soluble pigment producing a beautiful fluorescent solution.—The President exhibited photographs of four out of eight gigantic tortoises originally brought from Aldabra Island, and now living in the grounds of Government House, Seychelles, and communicated a report on the subject of the present distribution of the species, addressed to the Right Hon. Joseph Chamberlain, M.P., by the Administrator of the Seychelles.—Sir John Lubbock, Bart., M.P., F.R.S., read a paper on some Australasian collembola, figures of which were exhibited.—On behalf of Mr. F. N. Williams, the Secretary read a paper on some *Caryophyllaceae* from Szechuen, with a note on the recent botanical exploration of that province.—A paper was read by Mr. W. T. Calman on the Crustacean genus *Bathynella* (Vejd.), which was shown to be an ally of the important form *Anaspides* (Thom.) originally described in the Society's *Transactions*, vol. vi. p. 285.

**Zoological Society**, June 6.—Dr. Henry Woodward, F.R.S., Vice-President, in the chair.—Mr. Sclater exhibited photographs of the female specimen of Grévy's zebra now living in the gardens of the Société d'Acclimatation, Paris; and read a letter from Captain J. L. Harrington, H.B.M. Envoy to Abyssinia, in which he expressed a hope to be able to bring living examples of this animal home with him when he returned to this country.—Mr. A. Blaynay Percival exhibited and made remarks upon some specimens of birds and insects which he had recently brought from the southern districts of British Central Africa.—Mr. G. A. Boulenger, F.R.S., exhibited some living specimens of a Siluroid fish, the "Harmut" (*Clarias lazera*, C and V.), from Damietta, Egypt, collected by Mr. W. L. S. Loat, which were believed to be the first examples of this curious fish imported alive to this country.—Dr. S. F. Harmer, F.R.S., gave an account of specimens of the remains of a deer in the collection of the University Museum of Zoology at Cambridge, obtained from the Forest-Bed series at Pakefield, near Lowestoft, and belonging to the form usually known as *Cervus verticornis*, Dawk. The cranial portion of the skull was well preserved, and the antlers had a spread of six feet, measured in a straight line. The question of nomenclature was considered, with the result that *C. verticornis* of the Forest-

Bed was shown to be, probably, not identical with *C. carnutorum*, Laug., but a synonym of *C. belgrandi*, Lart.—Dr. A. Günther, F.R.S., gave an account of a collection of freshwater fishes made by Mr. R. B. N. Walker in the rivers of the Gold Coast. The collection, though a small one, was of considerable interest, as it contained specimens of several forms previously unknown from the Gold Coast. It had led the author to prepare a critical revision of the Gaboon species of *Chrysichthys*, which were numerous and difficult of discrimination. Eight new species were described in this paper, viz. *Petersius occidentalis* and seven species of *Chrysichthys*.—A communication was read from Dr. R. O. Cunningham, containing notes on the structure of Laborde's shark (*Euprotomicrus labordii*), an example of which had recently been presented to the museum of Queen's College, Belfast.—A communication was read from Mr. J. Stanley Gardiner, containing an account of the Astræid corals which he had collected in the South Pacific. The collection contained specimens of twelve genera and forty-eight species, six of the latter being new to science.—A communication was read from Dr. W. T. Blanford, F.R.S., containing the characters of several species of shells of the genera *Streptaxis* and *Ennea* from India, Ceylon and Burma. Of the former genus three species were described as new, bringing up the number of species of this genus, described from Southern India, to eleven. Of the genus *Ennea* two new species were described.

**Mathematical Society**, June 8.—Lord Kelvin, G.C.V.O., President, in the chair.—The President announced that the Council had awarded the De Morgan medal to Prof. W. Burnside, F.R.S., for his researches in mathematics, particularly in the theory of groups of finite order. Prof. Burnside, who was present, briefly returned thanks for the award, which had taken him by surprise.—Prof. Mittag Leffler, of Stockholm, a foreign member, was admitted into the Society, and made an interesting communication (in French) on the convergency of series. Prof. Elliott, F.R.S., Prof. Love, F.R.S., and Dr. Hobson, F.R.S., offered some remarks, to which Prof. Mittag Leffler replied.—The President spoke on "Solitary waves, equivoluminal and irrotational, in an elastic solid." In the course of his address he showed how greatly mathematicians were indebted to Sir George Stokes, F.R.S. Prof. Love said he had been much interested in the diagrams shown by Lord Kelvin. He afterwards gave a sketch of a paper by Prof. J. H. Michell on the transmission of stress across a plane of discontinuity in an isotropic elastic solid, and the potential solutions for a plane boundary.—The following papers were taken as read: On several classes of simple groups, Dr. G. A. Miller; on theta differential equations and expansions, Rev. M. M. U. Wilkinson; finite current sheets, Mr. J. H. Jeans; (1) on a congruence theorem having reference to an extensive class of coefficients; (2) on a set of coefficients analogous to the Eulerian numbers, Dr. Glaisher, F.R.S.; (1) the reduction of a linear substitution to its canonical form; (2) on the integration of systems of total differential equations, Prof. A. C. Dixon.

**Entomological Society**, June 7.—Mr. G. Verrall, President, in the chair.—Mr. J. J. Walker exhibited on behalf of Mr. G. F. Mathew a number of interesting Lepidoptera, chiefly from the Mediterranean region, and including amongst others the following: examples of *Thais polyxena*, Schiff., var. *ochracea*, Staud., having an unusually deep and rich colour, bred from larvæ found at Platæa, Greece; male and female of *Thestor ballus*, Hb., from Alexandria, the male remarkable in being largely marked with orange on the upper side of the front wings; and a singular aberration, from Corfu, of *Melitaea didyma*, Ochs., with central band of black spots very strongly marked on both wings, the other spots being obsolete and the ground colour pale fulvous.—Mr. E. E. Green exhibited a teratomorphic specimen of a zygænid moth, *Chalcosia venosa*, Walk., which he had found at rest on a leaf in Ceylon. In this specimen four wings were present on the left side, the hindmost being almost as fully developed as the normal hind wing on the right side, while the other three appeared to be attached to the meso-thorax. He also showed larvæ and pupæ of insects in air-tight glass tubes in which a little cotton wool, sprinkled with formalin, had been placed. The specimens, which had been thus preserved for nearly two years, had lost little of their original colour or brilliancy.—Mr. Gahan exhibited pupa-cases of a Longicorn beetle, *Plocederus obesus*, Gah., which were remarkable in being composed almost wholly of carbonate of lime. It was not known how the pupa-cases were fabricated, but presumably the larvæ must possess special lime-secreting glands.—Mr. R. McLachlan read a paper on a second Asiatic species of *Corydalis*, and exhibited the male type of the species described, which he proposed to name *Corydalis orientalis*. He said the first Asiatic species of *Corydalis* was described and figured by Prof. Wood-Mason in 1884, the genus up to that time having been considered to be peculiarly American. Mr. H. J. Elwes communicated a paper on the Lepidoptera of the Altai Mountains, and the Rev. A. E. Eaton a paper entitled "An annotated list of the *Ephemeridae* of New Zealand."

**Geological Society**, June 7.—W. Whitaker, F.R.S., President, in the chair.—On the geology of Northern Anglesey, by C. A. Matley; with an appendix on the microscopic study of some of the rocks, by Prof. W. W. Watts. The strata which occupy the northern part of Anglesey have been the subject of much controversy, some geologists considering them (with the exception of a few patches in the extreme north) to be pre-Cambrian, while others maintain that they are of Bala age, and that they are an upward continuation of the black slates that everywhere appear to underlie them to the south. The author attacks this problem from its palæontological as well as its stratigraphical side. The contortion, overfolding, cleavage, dislocation, and disruption which the rocks have undergone are described. Disruption is traced from its early stages into "crush-conglomerates." Some of the disrupted rocks are Ordovician, and traces of ancient dykes have been found rent to pieces by the movement, which is stated to be post-Ordovician and pre-Carboniferous. The detached masses of limestone and the isolated "quartz-knobs" of the northern complex are considered to be portions of strata which have suffered disruption in the same way as the thinner hard bands in the crush-zones. The appendix contains notes on some of the rocks from the Green series and the Ordovician system, the quartzites, and the crush-conglomerates.—On an intrusion of granite into diabase at Sorel Point (Northern Jersey), by John Parkinson. In the early pages the general character of this intrusion is described. Following this general introduction, the characters of the granite are described in some detail; then those of the diabase, formerly an ophitic dolerite. Details of structure of the granite in which absorbed basic material is present, and of the diabase into which acid material has permeated, are dealt with: particular attention being directed to the great alteration which the diabase has undergone—this has frequently amounted to a total reconstitution. In conclusion, points of resemblance and of difference are noted between this district and others; and an interesting slide from Alderney is described, showing the probable extension of such rocks in other directions.

EDINBURGH.

**Royal Society**, May 8.—Prof. Flint in the chair.—By request of the Council, Mr. C. W. Andrews, of the British Museum, gave an account of his expedition to Christmas Island, with special reference to its geology. The island seems to be a raised atoll resting on a basis of volcanic rocks and Miocene limestones, which in places are some hundreds of feet thick. The rocks forming the highest parts of the island are for the most part dolomitised, and the most recent of the deposits found are beds of phosphate of lime, which cap some of the highest hills on the east and north sides. Formerly existing as a group of islets with a central lagoon, Christmas Island has undergone a succession of movements of elevation, evidenced by the existence of a number of inland cliffs and terraces. At present a narrow fringing reef is forming round the greater part of the coast. The fauna and flora are specially remarkable for the large number of species peculiar to the island. Specially interesting are the two forms of rats (the one being fitted for climbing trees, and the other for burrowing), six species of land-crab, two bats (one flying at midday), several forms of pigeon, and numerous sea birds. As regards the flora, there was no difficulty in understanding how the seeds had originally found a lodgment in the island. One important part of the work of the expedition was to make a collection of the fauna and flora before the settlement of the island led to the introduction of foreign species and the modification or destruction of the endemic forms. Sir John Murray, in emphasising the importance of the scientific work carried out by Mr. Andrews, pointed out that Christmas Island was an illustration of how unexpectedly purely scientific inquiry led to a practical issue; for it was in the course of his investigations

into oceanic deposits that he discovered Christmas Island to be a storehouse of phosphate of lime.

May 16.—Prof. McKendrick in the chair.—Dr. C. G. Knott gave a short note on magnetic strains in bismuth. A slight indication had been obtained that there was a change of form in bismuth when strongly magnetised, but the indication was so slight that it was more prudent meanwhile to reserve judgment. —A communication by Mr. Omond on fog-bows, &c., seen at Ben Nevis since 1887, and a note on fog-bows by Prof. Tait were presented in continuation of former papers.—Mr. R. Forgan exhibited his practical method of enlarging and deepening the field of a compound microscope. The essence of the method consisted in shortening the distance between the object-glass and eye-piece, thereby obtaining a diminution of magnification with a corresponding increase of field. In short, the microscope was made to act somewhat after the fashion of a telescope. One interesting feature was the remarkable depth of focus obtained, so that the florets of a dandelion head could be seen throughout with great distinctness. The Chairman remarked that the form of microscope exhibited should prove very serviceable in the study of circulatory systems when high magnification was not desired.—The Rev. Prof. Duns, in a paper on some remains of Scottish early Post-Pliocene mammals, drew attention to the very important problems—zoological, climatological, and ethnographical—which were associated with the disappearance of animals in recent times. For example, what causes led to the disappearance of certain species, among whose remains no contemporaneous human remains were found? Did the absence of human remains necessarily imply that man had not appeared on the scene? The problems should be looked at both from the biotic and stratigraphical points of view; and it was most desirable that, in their characterisation of extinct species, experts should include a description of the physical and vital conditions of the localities in which these species occurred. The paper included a history and description of the fine mammoth tusk discovered near Ratho, Midlothian, in 1820, of the magnificent Greater Red Deer antlers discovered near Kingskettle, Fife, and other important relics now in the museum of the Free Church College, Edinburgh.

PARIS.

Academy of Sciences, June 12.—M. van Tieghem in the chair.—The jubilee of Sir G. G. Stokes and the centenary of the Royal Institution, by M. A. Cornu.—The angle of inclination of the sides studied with the aid of radioscopy and radiography both in morbid and healthy states, by MM. Ch. Gouchard and H. Guilleminot. The authors have studied more especially the appearances in cases of pleurisy. In recent unilateral pleurisy the diseased side has a smaller amplitude of oscillation than the healthy one, and the side is inclined at a greater angle.—Observations of shooting-stars, made at Athens, by M. D. Eginitis. The observations refer especially to the swarms observed on the nights of October 17, 18, November 3, 8, and 25, and December 6, 7, 11, 12, and 13.—On an extension of a theorem of Mittag-Leffler, by M. E. Phragmén. —Deformation of waves in the course of propagation, by M. P. Vieille.—On the equation of motion of automobiles, by M. A. Blondel.—Trials of instruments destined for experiments on the decimalisation of angles, by M. Caspari.—On the expansion of metallic alloys, by M. H. Le Chatelier. Alloys of copper and antimony, and copper with aluminium were studied, and the results expressed graphically in two curves.—The direct measurement of the osmotic pressure of very dilute solutions of sodium chloride, by M. A. Ponsot. The values found for the coefficient $i$ varied between 1·76 and 1·81, agreeing closely with the results obtained by Pickering by the freezing point method.—Rays emitted by an electrified point, by M. S. Leduc. The rays given off from a point connected with an electrostatic machine resemble the violet rays of the spectrum in their effects upon a sensitised plate.—Heat of oxidation of sodium, by M. de Forcrand. From the data given it would appear that the number currently admitted for the heat of oxidisation of sodium is too high by about 10 per cent.—On the estimation of hydrogen phosphide in gaseous mixtures, by M. J. Riban. A criticism of a recent paper by M. Joannis. The author contends that an acid solution of cuprous chloride acts perfectly satisfactorily as an absorbent for phosphoretted hydrogen, provided that care be taken to use an unoxidised product.—Action of iodine on alkalies, by M. E. Péchard.—Action of water upon the double iodides of mercury with potassium and ammonium, by M. Maurice François.—On copper reduced at low temperature, by M. Alb. Colson. Copper oxide reduced at 200° by hydrogen or by carbon monoxide, gives many reactions that do not occur with copper foil. Thus the metal catches fire in dry bromine, even at −21° C. If the copper is raised to above 280° C., or if exposed to moist air, it loses this property.—On mixed anhydrides of formic acid, by M. A. Béhal. By mixing formic acid and acetic anhydride, heat is evolved, and the cause of this is attributed by the author to the formation of a mixed anhydride, $CH_3.CO.O.CHO$, which can be isolated by treatment with petroleum ether and fractional distillation.—Contribution to the study of ivy; preparation of hederine, by M. Houdas. The glucoside hederine, $C_{64}H_{104}O_{19}$, obtained from ivy, gives on hydrolysis by dilute acids, rhamnose, a new sugar hederose, and a new substance $C_{26}H_{40}O_4$, to which the name of hederidine is given.—On the form *Oospora* (*Streptothrix*) of the *Microsporum* of the horse, by M. E. Bodin.—On a layer of magnetite with granite at Quérigut (Ariège), by M. A. Lacroix.—On the presence of iodine in the mineral waters of Royat, by M. A. Duboin. Iodine was not present in solution, but only in traces in organic compounds in suspension, ·04 mgr. iodine in 1 litre of water.—Bathymetric map of the Azores, by M. J. Thoulet.—Nervous oscillations following unipolar excitation; method for measuring their speed of propagation, by M. Aug. Charpentier.—Ivy and hederine; physiological and toxicological study, by M. A. Joanin.—New researches on the diastatic functions of indigo-bearing plants, by M. L. Bréaudat.—On a parasitic fungus in cancer, by M. J. Chevalier. A comparison of the organism isolated by the author, with that isolated previously from cancer growths by Dr. Bra, showed that the two parasites were absolutely identical.

## PETTIGREW ON THE LOCOMOTIVE.

*A Manual of Locomotive Engineering*. By William Frank Pettigrew, M.Inst.C.E.; with a selection of American and Continental Engines, by Albert F. Ravenshear, B.Sc., Whit. Sch. Pp. 430. (London: Charles Griffin and Co., Ltd., 1899.)

IT is with much pleasure we welcome this valuable addition to the literature of locomotive engineering—a subject seldom dealt with in text-books, and one which depends more on the results of experience than on theory as usually set forth in our technical schools. An author, therefore, in a position to deal with the subject in a satisfactory manner must of necessity have had a railway experience of no ordinary kind. In fact he must have gone through the mill in the form of the shops, works-management, and finally as locomotive superintendent. The author of this volume fills these requirements exactly, consequently we are not disappointed with his work.

In a volume consisting of about 400 pages we find the subject carefully treated, and divided into twenty-two chapters with three appendices. To commence with, we naturally find the pioneer forms of locomotives historically dealt with, and this is as it should be from the student's point of view; the credit, however, for earlier successes does not always appear to be given to the proper parties. The "Rocket," for instance, was a success mainly because of the multitubular boiler patented by William Henry James, and adopted by Stephenson in consideration of one-fourth share of the patent obtained by Losh and Stephenson for locomotive engines. The progress of earlier locomotives in the United States is also described—a very interesting subject when one remembers that "Old Iron Sides" was built by W. Baldwin in 1832, this maker being represented to-day by the eminent firm of the same name in Philadelphia.

On the subject of modern simple locomotives the author has a wealth of material at hand, that is to say, on single expansion engines. In Chapter ii., dealing with this branch of the work, we find a cursory definition of wheel-base, engine power, tractive force, boiler power, &c. (all of which are exhaustively treated later on in the work), after which very full and excellent descriptions of modern practice are given. The famous "Dunalastair" of the Caledonian Railway is mentioned; but more should have been said of this engine, for Mr. J. F. McIntosh, the able locomotive superintendent of that railway, is certainly the prophet of the big boiler in this country, and deserves mention for this reason. Other Scotch engines are described, including those of the Highland Railway, the illustrations of which do not include the louvres in the chimneys, "a fatal oversight." As an example of the older practice on the Manchester, Sheffield and Lincolnshire Railway, we find Mr. Charles Sacre's single express engine; we should have preferred the double-framed four-coupled bogie as a record of this eminent locomotive engineer. But why does the author omit the present practice on the Manchester, Sheffield and Lincolnshire, or rather the Great Central Railway, an example of which would have been interesting?

Chapter iii. deals with compound locomotives, and very fully does the author describe the various systems in vogue. Here this type of locomotive is uncommon, except on the North-Western Railway, where the Webb system is in use. Many experiments have been made on different railroads, but nearly all have returned to the simple type for express work, although for heavy goods traffic the Worsdell system is in use on the North-Eastern Railway.

On primary considerations of locomotive design we find much useful information, more particularly on train resistance, the author maintaining that the older formulæ are not sufficiently accurate, due to various causes, and proposes one which agrees fairly with practice, viz. $R = 9 + \cdot 007\ V^2$, where R is the resistance in pounds per ton, and V the speed in miles per hour. On the question of proportionate heating surface the author gives minimum values, and goes on to say, get as much as the design will allow. This is no doubt the right view to take, and locomotive engineers in this country are waking up to the fact that the bigger the boiler the more satisfactory the engine.

The author having been the works manager in the Nine Elms Works of the London and South-Western Railway Company for many years, one naturally expects to find all the detailed descriptions of parts of a locomotive very practical and concise. In Chapter v., dealing with cylinders and their parts, this expectation is fulfilled. A useful addition would be to add a simple test for cylinder metal, such as a tensile test of, say, 11 tons per square inch, or the regular shearing test of a 2-inch by 1-inch bar on supports 3 feet apart, to deflect three-tenths of an inch with a breaking load of not less than 35 cwt.

The conical form of piston-head shown in Fig. 69 was adopted by the late Mr. Stroudley to enable him to get as long a connecting rod as possible, and was usually made of gun-metal for the express engines. Many piston-heads are running made of wrought iron, a fact which the author fails to mention.

The descriptions of the arrangement of single and double slide bars are good, but we fail to read that the arrangement with four bars in Fig. 81 is the best when considered from the standpoint of weight of moving parts and balancing them. Further on, our author deals with connecting and coupling rods of various designs. Generally we find very little information as to the material used for these important details, and where steel is mentioned no tensile tests are given.

Chapter ix. deals with the important question of balancing the moving parts of a locomotive when in motion, and we must cordially congratulate Mr. Pettigrew on the very clear manner he has handled this important subject. The examples given are clear, and are worked out without unnecessary use of higher mathematics.

Valve gear, as dealt with in Chapter x., is of a purely descriptive nature, and includes the usual types. The Morton gear might have been included as a curiosity, as a goods engine has been satisfactorily running for some years on the North British Railway fitted with it. Of

valves of different descriptions we find much valuable information, including the piston type of valve, largely used at sea, and now, under the name of Smith's Patent, being experimented with on the North-Eastern and Midland Railways, the Highland Railway having tried and discarded it some short time ago. Valve gear in detail comes next, and we cannot agree with the author when he says that in inside cylindered engines expansion links with one bracket only are used. This is the exception and not the rule—*vide* the practice of the Brighton, Caledonian, and North British Railways.

Taken as a whole, the descriptions of all detailed work represent modern practice, and the engineering student will find much to learn in these pages. Chapter xiii. deals with the all-important question of the general construction and design of the locomotive boiler; after discussing the questions which really concern its dimensions, the question of various types is described. The now fashionable Belpaire type is badly illustrated in Fig. 155, which must represent an American or continental type of boiler, although the author does not say so, and the arrangement of stays and plating is certainly not of British design. The Belpaire boilers designed by Messrs. Neilson, Reid, and Company for the Mexican railways some years ago might be taken as fair representatives of this type of British design, and should be illustrated in a future edition—they being the prototype of some running on more than one British railway.

In order to allow freedom for expansion of the tubeplates of Belpaire boilers of British design, it is usual to arrange the last transverse rows of vertical stays so that any vertical movement of the fire-box will not be transmitted to the wrapper-plate; moreover, a similar arrangement might be placed above the door-plate with advantage.

On the use of steel in boiler construction we find much valuable information, but we most distinctly disagree with the author when he states on p. 200 that steel of boilerplate quality contains a maximum of 15 per cent. and a minimum of 10 per cent. of carbon! What has happened to the decimal point? The author, like many others, has not yet got over the idea that steel-plates require very special treatment in the flanging-shed and boiler-shop. This is not the case; steel-plates, as manufactured to-day, are more uniform in quality, and are certainly as easily worked as Yorkshire iron. On p. 215 we read that on the Caledonian Railway the roof of the fire-box is supported by vertical stays fastened in series of threes in a longitudinal direction. These stays were on the scrapheap years ago.

On the question of machine riveting, our author maintains that subsequent caulking of rivet-heads is unnecessary. If this is the case, why do our best firms of locomotive builders invariably carefully caulk every rivet-head before the boiler is tested? They work for a profit, not for honour and glory.

Mr. Ravenshear gives a very full description of continental and American locomotive practice, with illustrations, which will be found towards the end of this volume, besides the usual descriptive accounts of the vacuum and Westinghouse railway brakes. Taken as a whole, this work is one of the best of its kind that has been published on the subject. The strains experienced by various parts of a locomotive during work are impossible to calculate, and, therefore, it must be every-day experience that can train the successful designer. For this reason a text-book on this subject can only be descriptive of work done which successfully withstands the usages of every-day work.

NORMAN J. LOCKYER.

## THE HEREFORD EARTHQUAKE OF 1896.

*The Hereford Earthquake of December* 17, 1896. By Charles Davison, Sc.D., F.G.S. Pp. xi + 303. (Birmingham: Cornish, 1899.)

AFTER an interval of more than two years Dr. Charles Davison has at last given us, in a volume of 303 pages, his long-promised account of the earthquake which, in the early morning of December 17, 1896, rudely awakened the inhabitants of the Severn Valley.

When we look at the 2902 epitomised accounts which Dr. Davison has brought together respecting an earthquake which in many countries would have been regarded with as much indifference as a sprinkling of rain, we are inclined to ask whether the examination of this long series of remembrances, obtained from a community more or less excited by phenomena with which they had but little experience, would be likely to lead to results of any value. Had this earthquake originated in a sparsely populated country where there were difficulties in obtaining accurate time, the analysis of observations taken under such conditions would, to a large extent, have been labour in vain.

Although no special provisions are taken in Britain for the observation of earth tremors, as the one now under consideration occurred at the waking hour of many millions of people who, lying on their beds, were in the best possible position for noticing slight vibrations, and for the most part had the means of obtaining fairly good time, and above all were intensely interested in the phenomenon they experienced, the conditions for obtaining a large series of valuable records were unusually favourable. Within the epifocal area where chimneys fell or were "hurled to some distance"—which we doubt—and buildings were unroofed, and within at least one hundred miles of the same, all the observers had but little doubts as to the nature of the movements they experienced. Beyond these limits in very many instances it is likely that many observers only realised and remembered that a something or other had rattled, perhaps the window or a lamp-shade, after they had read their morning papers, and with feelings of satisfaction as participants in an alarming disaster, they threw in their notes and helped to complete an important chapter in British seismology. If every time a window was slightly shaken, glasses rattled, or other unaccountable microphonic disturbances were perceptible could be recorded, and the collected results analysed, it is extremely probable that the seismic register for the British Islands would be considerably increased.

Before discussing the catalogue of observations, Dr. Davison sets out by showing that there is a reality of connection between the majority of earthquakes and the

slow but intermittent growth or extension of faults. This done, he draws on a map isoseismals or curves surrounding all places at which the intensity of the movement, as represented in certain cases by its destructivity, has been approximately equal. The most important of these is isoseismal number 8, which is the innermost and contains some seventy-three places at which there was structural damage. It is oval or elliptical in form, with its major axis forty-three miles in length running from N.W. to S.E., and encloses the towns of Hereford, Ross and Gloucester. Outside this are the isoseismals numbered 7, 6, 5 and 4, a series which become more and more circular in form, the latter extending beyond Wexford and Dublin in the west, and Norwich on the east.

From the form of these isoseismals, especially that of No. 8, which is the most important, by reasoning familiar to seismologists it is shown that the disturbance originated along a line of fault which dips to the north-east, and has a strike coinciding with the major axis of the innermost of these curves of equal intensity.

It appears that two series of vibrations were noted, which at different places were different in intensity and duration. An examination of the records relating to these leads to the conclusion that the principal shock originated from two foci along the line of fault, one near to Hereford, and the other near to Ross.

At this point Dr. Davison is hand in hand with the geologist who, having already mapped faults bounding the triangular area of May Hill, south-east of Hereford, now sees that there are good reasons for supposing that one of these is but the south-eastern extension of that revealed by the distribution of vibrational effects accompanying the Hereford earthquake. Davison's fault therefore throws new light upon the geotectonic relationships amongst the older rocks in Western Britain, and that there is such a rupture in the Old Red Sandstone to the east of Hereford may at any time be of importance not only to the geologist but to the engineer.

Another set of lines discussed are those passing through places at which the same phase of the earthquake was felt at the same instant. These are the well-known coseismal lines, which are less elongated than the isoseismals, but have their major axis in approximately the same direction. From the distances between them, velocities of transit varying between 2814 and 3095 feet per second are calculated, suggesting, but not on very certain grounds, an apparent increase in the velocity of earthquake transmission as it radiates. With a knowledge of the velocity between any two coseismals and the distance of one of them from the epicentre, the time of origin of the earthquake is determined as having been at 5h. 31m. 45s. a.m.

To the seismologist, the most striking feature in Dr. Davison's work is his treatment of the sound phenomena. Mr. Mallet in his classical work on the Neapolitan earthquake of 1857 gives us a chapter on the sounds that attend a shock, and which are produced by steam or by the rending of rocks. In a previous publication, Dr. Davison has given us his views as to the origin of earthquake sounds, which he attributes to the slipping or mechanical disturbance in the marginal region of the seismic focus.

In the present work, he gives us a map showing isacoustic lines or lines of equal sound intensity. Any one of these lines passes through districts in which the percentage of observers who noted a sound are equal, and they are therefore more strictly speaking, as the author states, lines of equal sound audibility.

The major axis of these closed curves is, roughly speaking, at right angles to that of the iso- and coseismal curves. More accurately it is a hyperbolic trace which follows the band, along which it is shown that the two series of vibrations from the two earthquake foci are superimposed.

The general result arrived at from the study of these isacoustic lines is that they confirm the conclusion that there were two distinct, or nearly distinct, regions along the fault line from which vibrations radiated, and that the slip at the northern end of this line occurred a few seconds earlier than at the southern end. In this discussion of sound phenomena we have something distinctly original.

The shock was felt less upon hard rocks and on high ground than on soft ground and in valleys. In the Bangor-Anglesey district the shock was felt most powerfully upon the carboniferous and ordovician rocks, and less upon the volcanic materials and schists. It was felt underground in several mines; at some places it produced feelings of nausea, and many instances are recorded of horses, cows, dogs, sheep, pheasants and other birds having exhibited symptoms of alarm.

Without going further into Dr. Davison's work, taking the same as a whole, he is to be congratulated on having extracted from materials which at first sight are of very little promise a quantity of valuable and novel information. The Hereford earthquake was a transient shivering of an exceedingly small portion of the earth's crust; and, considering that there may be 10,000 of these occurring every year, this one appears to have been more carefully studied than any of its predecessors of equal magnitude.

Had the author contented himself with analysing half the facts he has collected, although the same would have made a column of print 100 yards in length, the probability is that, beyond noting a number of incidents of local interest, our knowledge of seismic phenomena would have not been materially increased. As it is, especially perhaps with regard to isacoustics, a distinct advance has been made, and in the future we shall find others working on similar lines. J. MILNE.

## *A BIOLOGICAL RECORD.*

*L'Année Biologique.* Comptes rendus annuels des travaux de Biologie générale, publiés sous la direction de Yves Delage, professeur à la Sorbonne, avec la collaboration d'un Comité de Rédacteurs. Secrétaire de la rédaction, Georges Poirault, Docteur ès sciences. Première année (1895). Pp. xlv + 732. 1897. Deuxième année (1896). Pp. xxxv + 808. 1898 (Paris: Schleicher Frères.)

IN one of the Woods Holl Biological Lectures, entitled "Bibliography: a Study of Resources," Dr. Charles Sedgwick Minot, himself the author of one of the standard zoological bibliographies, compares the biological biblio-

grapher to an explorer in a forest "who finds no open way to travel, but must laboriously hunt for his specimens . . . as they lie scattered, unclassified, and, all too often, concealed." These words were spoken in 1895, but now the two bulky volumes before us show that the biologist need not lose hope in the ever thickening jungle of literature. They form a thoroughly competent biological record for two years, and, whatever may be their defects in detail, they deserve a hearty welcome. If Prof. Delage's undertaking is supported as it should be, not only by subscribers, but by co-operators, it should do much in the future to widen the interest of naturalists in the great problems of biology, to raise the standard of biological scholarship, and to curb the impatience of those who hasten to ill-advised reiteration of tales many times told.

This "biological record" does not compete with its seniors—the *Zoological Record*, the Naples *Jahresbericht*, and others akin, nor with the Zürich Concilium over which Dr. Field presides, nor with the *Journal of the Royal Microscopical Society*, the *Zoologisches Centralblatt*, and their like, for, as the title indicates, it aims at recording and summarising and appreciating those papers which deal with or have a bearing on *general biological problems.* It is a record for biologists, not for systematists, anatomists, physiologists, embryologists, and palæontologists, who have their own "resources"—though none would be the worse of availing himself of this also.

The task is somewhat similar to that which has been attempted for many years in the first part (General Subjects) of the *Zoological Record*, and in the corresponding portion of the Naples *Jahresbericht;* but there are several notable differences. The meshes of the net used by *L'Année Biologique* are finer than in the others ; it is botanical and anthropological as well as zoological ; and there are more or less adequate signed summaries of all the important papers recorded. On the other hand, it is only fair to notice that the Records which are issued from the Zoological Society of London, by the Naples station, and by the botanists, come much more nearly up to time. Thus, we must be ungrateful enough to observe that the third volume of *L'Année Biologique* dealing with 1897 is not yet to hand ; and it is of course obvious that the editors of the later records have the advantage, which no one grudges, of being able to utilise the labours of their more up-to-date predecessors.

What the editors understand by the term "biological" is at once seen from the table of contents, which includes about a score of subjects : the cell ; the sex-cells and fertilisation ; parthenogenesis ; asexual reproduction ; ontogeny ; teratogeny ; regeneration ; grafting ; sex ; polymorphism, metamorphosis, and alternation of generations ; latent characters ; correlation ; death, immortality, and the germ-plasm ; general morphology and physiology ; heredity ; variation ; origin of species ; geographical distribution ; nervous system and mental functions ; and general theories. It is easy to criticise, but it seems to us that this classification is unwieldy, and it has certainly led to an unnecessary amount of repetition. We notice, for instance, at least one case where the same paper has been summarised twice at considerable length by different recorders, which, however interesting, is luxurious.

Prof. Yves Delage and Dr. Georges Poirault deserve the gratitude of all biologists for their monumental record, though perhaps only bibliographers will adequately appreciate the magnitude of the labour involved. It is of course a co-operative work, organised from the contributions of a large body of workers in Europe and America, and, as our own share has been a minimal one, we are bold to say that the co-operators also deserve some gratitude for their labour of love. An interesting and valuable feature is the general discourse which precedes most of the sections, sometimes rising to the dimensions of a comprehensive essay, as in the case of correlation, phagocytosis, and geographical distribution. There seems, indeed, just a hint of overdoing this part of the record.

Every one will agree that the prime and indispensable virtue of any bibliography is accuracy, and in this respect we must in honesty say that there is still room for improvement in *L'Année Biologique.* We took the trouble to correct three pages in the first volume, and the result is certainly not beautiful to look upon. We hasten, however, to add that the inaccuracies affect the letter rather than the spirit of the bibliographer's laws, and that the second volume has attained to a high standard. We ourselves well know how insidiously mistakes creep in, and we are in no mood for fault-finding, yet it must be remembered that accuracy comes first in the criteria of bibliographic work. With a task so huge, the only hope is that there may be more generous co-operation. Surely some of those who make game of a busy recorder's mistakes might sometimes remember that amelioration for the future will be furthered by the simple device of sending in copies of their works to be at hand both in the compilation and in the proof-reading of the record.

Since the volumes before us were published, we have thoroughly tested their usefulness, and, frankly, we cannot but be surprised if every serious biologist does not agree with us in calling them indispensable. As for those gay knights-errant who care not for any of these bibliographies, we can only regret that they thereby do injustice to their genius.

And, finally, we should say in welcoming this biological record, that as there is a social as well as a scientific aspect of bibliography, it seems to us a matter for genuine congratulation that the editors have endeavoured to place their record upon an international basis—an endeavour which will, we hope, eventually have further development in an increasing recognition of the cosmopolitanism of science.

J. A. T.

## OUR BOOK SHELF.

*A Short History of Astronomy.* By Arthur Berry, M.A. Pp. xxxi + 440. (London : John Murray, 1899.)

READERS of this volume will probably be divided into two classes, those who are pleased with any description of a subject, however disconnected, and those who wish the whole of the ground to be covered, even though many details may only be slightly touched upon. To the former the book will offer much pleasant reading, but it is likely that the latter will be disappointed with the treatment of the matter as it is here presented.

Chapter i. is entitled "Primitive Astronomy," much of the space, however, being taken up by explanations of the various definitions of the celestial sphere. Considering the amount of painstaking labour which has been devoted by many modern inquirers to proving the extent of the astronomical knowledge of the Egyptians and other ancient nations, as evidenced by their temples and monuments, it is rather hard to be told that this is but "a plausible interpretation of these peculiarities."

Chapter ii., dealing with "Greek Astronomy" from 600 B.C. to 400 A.D., is much more readable. Commencing with the introduction of the calendar and its various alterations, the successive celestial systems figured out by Plato, Aristotle, Aristarchus, Hipparchus, Ptolemy, &c., are very lucidly explained. The comparatively slow development of astronomy during the Middle Ages, from 600 A.D. to 1500 A.D., forms the subject of Chapter iii. Towards the end of this period, the first authentic conceptions of the celestial bodies being situated on concentric crystal spheres were enunciated.

The fourth chapter is entirely devoted to the enormous impetus given to astronomical knowledge by the teachings and work of the great Copernicus, extending over the period 1473 A.D. to 1543 A.D. The succeeding five chapters deal with the life-works of Tycho Brahe (1543-1601), Galilei (1564-1642), Kepler (1571-1630), and Newton (1643-1727).

Chapter x. deals with the progress of observational astronomy during the eighteenth century, the chief workers during this period being Flamsteed, Halley, Bradley, Maskelyne and Lacaille; while the following chapter reviews the mathematical aspect of the science for the same epoch, Euler, D'Alembert, Lagrange and Laplace occupying the places of honour.

Chapter xii. is devoted to the work of Herschel from 1738 to 1822. These few chapters are extremely interesting, but it is very disappointing to find that the astronomical progress of the nineteenth century is crowded into the remaining fifty pages. Considering the enormous advances made during this period, this is wholly out of proportion, and in consequence many important matters have either been merely mentioned or omitted altogether. For example, although the book is sufficiently up to date to mention the discovery by Prof. Nasini of a terrestrial gas whose spectrum contained a line probably coincident with the chief coronal line, it is distressing to find no mention whatever made of the gigantic Draper Catalogue of Prof. Pickering dealing with the classification of stars according to their spectra; indeed, the only reference to photographic work on stellar spectra is in connection with motion in the line of sight. Again, the whole matter of the organisation, &c., of the great photographic survey is contained in twelve lines. The mathematical portions of the science are, however, treated much more generously.

The author has attempted a very difficult task in condensing the whole history of astronomy into so small a volume, and it is from this standpoint that the book must be judged. Although to the individual there is much that is unsatisfactory, the work contains a great amount of useful information, which will no doubt cause it to find favour.

*Outlines of Physical Chemistry.* By A. Reychler. Translated by John McCrae, Ph.D. Pp. xvi + 276. (London and New York: Whittaker and Co., 1899.)

THE choice and arrangement of the subject-matter of this book is fairly satisfactory. It includes the laws of chemical combination, the atomic hypothesis, the gas laws, vapour density, the specific heat of solids and the periodic system. The second part contains a fuller discussion of the properties of gases and the critical phenomena, the connection between chemical constitution and the boiling point, volume, refraction and rotation of liquids, and the properties of solutions. The third part deals with thermo- and electro-chemistry and the nature of solutions of salts. The fourth part treats of chemical equilibrium and the velocity of reactions. The treatment of this subject-matter does not, however, appear to be distinguished by any striking originality or other special merit which would warrant the translation of the book. On p. 2, the law of constant proportions is stated thus: "In order to form a substance, it is always necessary to have the same elements united in the same proportions." This is much the same as saying that any two samples of the same kind of matter have the same composition. As Mr. Hartog pointed out in these columns, a correct statement of the law of constant proportions should emphasise the view, upheld by Proust, that the proportions in which two substances combine alter *per saltum*, and that there is not (as Berthollet believed) a series of compounds of all intermediate compositions bridging over the gaps.

It might have been mentioned that the conclusions drawn by Traube from his work on the volumes of liquids (pp. 66-70) are not universally accepted.

The account given of the reasons for assuming the existence of free ions in electrolytes is so incomplete as to be misleading. The work of Clausius is not mentioned, and the considerations which led Arrhenius to his extension of the hypothesis of Clausius do not receive much better treatment.

The evolution of heat accompanying the solution of substances like hydrochloric acid or caustic soda in water is regarded by the author as an insuperable objection to the ionic hypothesis in its usual form. To overcome this objection he proposes a modified hypothesis in which the sodium ion in solutions of sodium salts, for example, is supposed to be combined with an hydroxyl group. In order to explain the phenomena of electrolysis, the charged sodium ion is supposed to be continually passing from one hydroxyl group to another; an exactly similar supposition, however, led Clausius to assume that the ions spend at least some portion of their existence in the free state, so that the author's modification appears to consist in the addition of a new (and unnecessary) hypothesis to the old one. A discussion of this kind is, in any case, somewhat out of place in a book intended for beginners.

The translation might have been better; we do not like "luminary vibration" (p. 81); "the ascension of the mercury" in a thermometer (p. 137); "measurement instruments" (p. 189); "the comparativeness of our results" (p. 197); "electrolysable compounds" instead of electrolytes; "this scientist" (presumably *ce savant* in the original); "the momentary course of the reaction" (p. 249) instead of the velocity of the reaction at a given instant.

*Views on Some of the Phenomena of Nature.* By James Walker. Part II. Pp. vi + 187. (London: Swan Sonnenschein and Co., Ltd.)

AMONG the views expressed are that "Light is the sensation produced through the medium of the organ of vision by the action of multitudinous effluvia, exhaled by the sublimation of the incandescent substances which exist in the sun's photosphere, and which are borne into space by an eruptive force, emanating from the contracting body of the sun." After a review of a number of scientific and unscientific statements, the book concludes with the question "As to the 'mode of motion' theory of heat, or the 'wave' theory of both light and heat, of electricity and ether, is it any more than a fiction of the imagination?" Persons who would reply in the negative will be impressed by the arguments of Mr. James Walker.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### Physical Measurement of Public Schoolboys.

I ENCLOSE photographs of two lecture diagrams which were used for a paper on the physical development of public schoolboys read to the Medical Officers of Schools Association last Easter. The curves represent the various different schemes of growth followed by schoolboys from the age of $10\frac{1}{2}$ to $18\frac{1}{2}$, according as they are developing into large, small, or medium sized men. They are constructed from corresponding series of curves of distribution, which curves are constructed from a large number of observations recorded at various public schools. From 14,000 to 15,000 observations have been collated for the construction of each series, and I regard them as being fairly trustworthy in form between the ages of 12 and 18. Beyond these limits the form of the curves may be slightly at fault, owing both to insufficient number of observations and to the process of natural selection which influences the physical status of the majority of boys who come early and stay late at a public school. The curves in Fig. 1 are constructed by marking off on the vertical line through each age the various heights at which the curve of distribution for that age crosses the 5 per cent., 10 per cent., 15 per cent., . . . 95 per cent. lines. Each series of corresponding points is then joined up by a flowing curve, with the result shown. The central line, between the numbers 10 and 11, shows where the various curves of distribution cross the 50 per cent. line, and consequently indicates the scheme of growth of the mean boy.

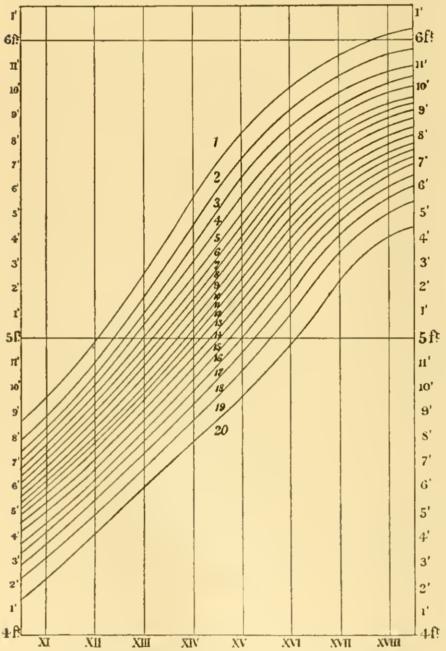

FIG. 1.—Grade curves for height of public schoolboys from $10\frac{1}{2}$ to $18\frac{1}{2}$ years of age. The figures on the base line refer to age. The figures down the centre of the diagram are the numbers of the grades, which are bounded by the two curves between which the several numbers are placed. There is no lower limit to grade 20, nor upper limit to grade 1.

It was contended in the paper that since each of these curves represents the growth of a boy, who develops in such a manner as to preserve always the same relative position amongst his fellows, they give an accurate idea of the growth which may be reasonably expected from a boy at any stage of his development, whatever his physical status may be. A glance at the diagram will show that the rate of growth, which is measured by the pitch of the curves, varies considerably for boys of the same age but of different physique. The period of maximum growth is reached much sooner by a boy of a high grade than by one of a low grade, and lasts much longer. Thus the steepest pitch of the topmost curve occurs between the ages of $13\frac{1}{2}$ and $14\frac{1}{2}$, and is sensibly uniform during that period, the corresponding steepest pitch in the mean line lies between the ages of 15 and $15\frac{1}{2}$, in the lowest line it lies between $16\frac{1}{2}$ and 17. Consequently, during the period of fastest growth, all boys may be expected to grow at nearly the same rate; but this rate of growth is reached by some boys three or four years later than by others.

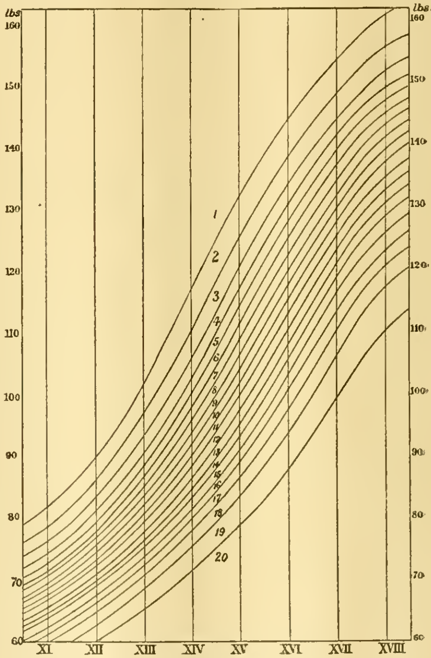

FIG. 2.—Similar grade curves for weight.

Fig. 2 represents the corresponding series of curves for weight, and teaches much the same lessons; it is evident, however, that the rate of growth in height declines much more rapidly after the period of maximum growth is passed than the rate of growth in weight, consequently boys of the same height but of different ages may be expected to differ considerably in weight. That this is generally the case was clearly shown by another set of curves exhibited at the lecture.

The curves shown have been used for constructing tables of grades, by means of which the limits of twenty grades are fixed, in some one of which a boy can be immediately placed if his measurements are known. From the mode of construction it is evident that, *à priori*, each of these grades is equally probable. The tables have in actual practice been found to be of great use in estimating the progress of individuals, and of gymnastic

classes, &c. Thus an analysis of the grades o. chest-girth of 255 boys before and after a three terms' course of compulsory gymnastics showed that the following improvement had been made. The numbers in the lower line give the percentage of the boys examined, who made the number of grades improvement indicated in the line above.

| Improvement :— | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| 1 gr. | 2 gr. | 3 gr. | 4 gr. | 5 gr. | 6 gr. | 7 gr. | 8 gr. | 9 gr. | 10 gr. | 11 gr. |
| Per cent. :— | | | | | | | | | | |
| 11 | 11 | 12 | 10 | 7 | 6 | 4 | 4 | 1 | 4 | 1 |

This with the omitted fractions gave 73 per cent. of the boys who had made more or less marked improvement relative to the general mass of boys of their age, the improvement in some cases being very marked indeed.

An analysis of the growth of 161 boys by means of their grades showed that the scheme of growth corresponded to the scheme indicated by the curves in the diagram in 31 per cent. of the cases examined. There was a steady rise relative to this standard in 17 per cent.; a steady fall in 10 per cent.; a period of rise followed by one of fall, or *vice versâ*, in 18 per cent. In 9 per cent. the variation was erratic, and the remaining 15 per cent. probably belonged to the first group; but not within the limits of variation allowed.

In 68 per cent. the type of structure, as indicated by the relation of height to weight, was stable throughout the period examined; but in about one-fourth of these cases there was a considerable constant difference between the grades of height and weight, amounting in the most extreme cases to as much as eight grades.

The lesson drawn from these observations was that, in order to form a correct opinion relative to a boy's physical progress by means of his measurements, it is very desirable to keep a regular record of his growth, in order that the general scheme of his growth may be determined, and that any irregular fluctuations due to external and removable causes may be noted and properly dealt with. C. H.

### The Giant Tortoises of the Galapagos.

I NOTICED in your issue of June 15 a paragraph about the Galapagos tortoises. I do not know if this information is of any interest, but during my residence in Hawaii I knew of two living there. One of them lived in a garden near Hilo, and belonged to the late Captain Thomas Spencer; I last saw it about 1880. The other one lived on the Waimea plains in a perfectly wild state, and I used frequently to come across it when out shooting. It used to wander about within a radius of three or four miles.

It was blind of one eye, and its shell had lichen growing on it, and it could move about with a man sitting on its back.

I last saw it in 1890, but it may possibly be still living; this, however, could easily be ascertained.

They were, I believe, brought to Hawaii from the Galapagos in whalers, and were of great age. If desired, I shall endeavour to find out if they are still alive. W. HERBERT PURVIS.

10 Alexandra Place, St. Andrews, Fife.

### School Laboratory Plans.

COLLEGE plans are not always safe precedents. Boys need more supervision. Can any of your readers advise as to the best arrangement of benches for a class of twenty-four to thirty boys, aged fourteen to seventeen, doing chemistry and physics with elementary quantitative experiments?

(1) Is the double back-to-back bench the best form? It may economise woodwork, but it makes the class face both ways, and attention to verbal instruction is less easy.

(2) Is the superstructure of shelving necessary? If qualitative analysis is not done, fewer bottles are needed. The superstructure hinders conversation across double benches, but it stops supervision also.

(3) What is the best way of arranging the benches so as to allow of supervision and keep wall spaces free for shelving? They may be (*a*) all round the wall, leaving no space for shelves and cupboards; or (*b*) single bench along two walls and double bench down the middle; or (*c*) across the room, double benches alternating with windows, well lighted but difficult to supervise; (*d*) central aisle with double bench extending to walls right and left; (*e*) double benches, lengthways, free from walls; (*f*) single benches, cross-ways, like the desks of an ordinary class-room.

I shall be grateful for any help or advice.

Bootham School, York, June 23. HUGH RICHARDSON.

### Pair of Brazilian Marmosets Breeding in England.

A PAIR of marmosets, which for the two past winters have had a free run of our greenhouse and garden (in Buckinghamshire), produced two young ones on May 24. They seem to thrive on freedom and exercise, and the young ones are now beginning to feed themselves. In hot weather they like to remain out all night, but at first they came in to their box in the greenhouse every evening, the male parent always carrying the twins on his back, their little round furry heads merely looking like small excrescences each side of his neck; and only handing them to the mother at feeding-times, and then carefully lifting them back with both hands and settling them into position, where they seem to cling on without being held.

Their favourite garden house appears to be an old bird's nest, rather high up in a pink thorn-tree, some distance from the greenhouse. They very rarely come down to the ground, but the female will answer a call and come to feed from the hand. Bananas, milk and water, insects and young birds are the foods they like best. DORA WHITMORE.

## *THE DIFFRACTION PROCESS OF COLOUR-PHOTOGRAPHY.*

THE production of colour by photography has been accomplished in two radically different ways up to the present time. In one, the so-called Lippmann process, the waves of light form directly in the photographic film laminæ of varying thickness, depending on the wavelength or colour of the light. These thin laminæ show interference colours in reflected light in the same way that the soap-bubble does, and these colours approximate closely to the tints of the original.

The technical difficulties involved in this process are so great that really very few satisfactory pictures have ever been made by it. The other, or three-colour process, has been developed along several distinct lines, the most satisfactory results having been produced by Ives with his stereoscopic "Krōmskōp," in which the reproduction is so perfect that, in the case of still-life subjects, it would be almost impossible to distinguish between the picture and the original seen through a slightly concave lens. The theory of the three-colour method is so well known that it will be unnecessary to devote any space to it, except to remind the reader of the two chief ways in which the synthesis of the finished picture is effected from the three negatives. We have first the triple lantern and the Kromscope in which the synthesis is optical, there being a direct addition of light to light in the compound colours, yellow being produced, for example, by the addition of red and green. The second method is illustrated by the modern trichromic printing in pigments. Here we do not have an addition of light to light, and consequently cannot produce yellow from red and green, having to produce the green by a mixture of yellow and blue. Still a third method, that of Joly, accomplishes an optical synthesis on the retina of the eye, the picture being a linear mosaic in red, green and blue, the individual lines being too fine to be distinguished as such.

The diffraction process, which I have briefly described in the April number of the *Philosophical Magazine*, is really a variation of the three-colour process, though it possesses some advantages which the other methods do not have, such as the complete elimination of coloured screens and pigments from the finished picture, and the possibility of printing one picture from another. The idea of using a diffraction grating occurred to me while endeavouring to think of some way of impressing a surface with a structure capable of sending light of a certain colour to the eye, and then superposing on this a second structure capable of sending light of another colour, without in any way interfering with the light furnished by the first structure. This cannot, of course, be done with inks, since if we print green ink over red, the result will not be a mixture of red light and green

light, but almost perfect absence of any light whatever; in other words, instead of getting yellow we get black. Let us consider first how a picture in colour might be produced by diffraction. Place a diffraction grating (which is merely a glass plate with fine lines ruled on its surface) before a lens, and allow the light of a lamp to fall upon it. There will be formed on a sheet of paper placed in the focal plane of the lens, an image of the lamp flame, and spectra, or rainbow-coloured bands on each side of it. Now make a small hole in the sheet of

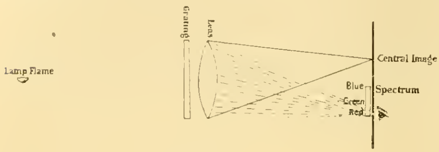

FIG. 1.

paper in the red part of one of these spectra. This hole is receiving red light from the whole surface of the grating, consequently if we get behind the paper and look through the hole we shall see the grating illuminated in pure red light over its whole extent. This is indicated in Fig. 1, where we have the red end of the spectrum falling on the hole, the paths of the red rays from the grating to the eye being indicated by dotted lines. Now the position of the spectra with reference to the central image of the flame depends on the number of lines to the inch with which the grating is ruled. The finer the ruling the further removed from the central image are the coloured bands. Suppose now we remove the grating in Fig. 1, and substitute for it one with closer ruling. The spectrum will be a little lower down in the diagram, and instead of the red falling on the hole, there will be green; consequently, if we now look through the hole, we shall see this grating illuminated in green light. A still finer ruling will give us a grating which will appear blue. Now suppose that the two first gratings be put in front of the lens together, overlapping as shown in Fig. 2. This combination will form two overlapping spectra, the red of the one falling in the same place as the green of the other, namely on the eye-hole. The upper strip, where we have the close ruling, sends

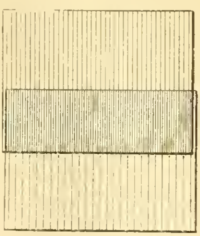

FIG. 2.

green light to the eye and appears green; the under strip, with the coarser ruling, sends red light to the eye and appears red, while the middle portion, where we have both rulings, sends both red and green light to the eye, and in consequence appears yellow, since the simultaneous action of red and green light on any portion of the retina causes the sensation of yellow. In other words, we have in superposed diffraction gratings a structure capable of sending several colours at once to the eye.

If we add the third grating, we shall see the portion where all three overlap illuminated in white, produced by the mixture of red, green and blue light.

Three gratings with 2000 lines, 2400 lines, and 2750 lines to the inch, will send red, green and blue light in the same direction, or, in other words, to the same spot on the screen behind the lens.

Suppose, now, we have a glass plate with a design of a tulip, with its blossom ruled with 2000 lines to the inch, its leaves ruled with 2400, and the pot in which it is growing ruled with 2750 lines, and place this plate before the lens. On looking through the hole we shall see a red tulip with green leaves growing in a blue pot. Thus we see how it is possible to produce a coloured picture by means of diffraction lines, which are in themselves colourless. Those portions of the plate where there are no lines send no light to the eye, and appear black.

We have now to consider how this principle can be applied to photography. That photographs which show colour on this principle can be made, depends on the fact that a diffraction grating can be copied by contact printing in sun-light, on glass coated with a thin film of bichromated

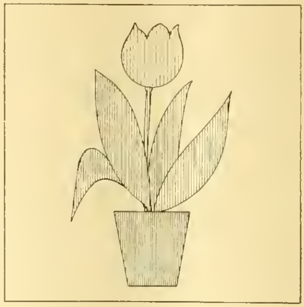

FIG. 3.

gelatine. The general method which I have found best is as follows. Three gratings ruled on glass with the requisite spacing were first prepared.[1]

To produce a picture in colour three negatives were taken through red, green, and blue colour filters in the usual manner. From these three ordinary lantern-slide positives were made. A sheet of thin plate-glass was coated with chrom gelatine, dried, and cut up into pieces of suitable size; one of these was placed with the sensitive film in contact with the ruled surface of the 2000-line grating, and the whole covered with the positive representing the action of the red light in the picture. An exposure of thirty seconds to sunlight impressed the lines of the grating on the film in those places which lay under the transparent parts of the positive. The second grating and the positive representing the green were now substituted for the others, and a second exposure was made. The yellows in the picture being transparent in both positives, both sets of lines were printed superposed in these parts of the picture, while the green parts received the impression of 2400 lines to the inch only.

The same was done for the blue, and the plate then washed for a few seconds in warm water. On drying it appeared as a coloured photograph when placed in front of the lens and viewed through the hole in the screen.

[1] These gratings were ruled for us on the dividing engine at Cornell University, through the courtesy of Prof. E. L. Nichols.

Proper registration during the triple printing is secured by making reference marks on the plates. A picture of this sort once produced can be reproduced indefinitely by making contact prints, since the arrangement of the lines will be the same in all of the copies as in the original. The finished picture is perfectly transparent, and is merely a diffraction grating on gelatine with variable spacing. In some parts of the picture there will be a double grating, and in other parts (the whites) there will be a triple set of lines. Having had some difficulty in getting three sets of lines on a single film in such a way as to produce a good white, I have adopted the method of making the red and green gratings on one plate, and the blue on another, and then mounting the two with the films in contact. It is very little trouble to multiply the pictures once the original red-green grating picture is made.

The pictures are viewed with a very simple piece of apparatus, shown in Fig. 4, consisting of a lens cut square like a reading glass, mounted on a light frame provided with a black screen perforated with an eye-hole through which the pictures are viewed. The colours are extremely brilliant, and there is a peculiar fascination in the pictures, since if the viewing apparatus be slowly turned so that its direction with reference to the light varies, the colours change in a most delightful manner, giving us, for example, green roses with red leaves, or blue roses with purple leaves, a feature which should appeal to the impressionists. The reason of this kaleidoscopic effect is evident, for by turning the viewing apparatus we bring the eye into different parts of the overlapping spectra.

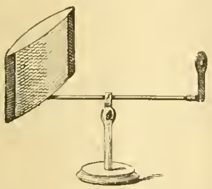

FIG. 4.

It is possible to project the pictures by employing a very intense light, and placing a projecting lens in place of the eye behind the perforation in the screen. Of course a very large percentage of the light is lost, consequently great amplification cannot well be obtained. I have found that sun-light gives the best results, and have thrown up a three-inch picture on a four-foot sheet so that it could be seen by a fair-sized audience.

By employing a lens of suitable focus it is possible to make the viewing apparatus binocular, for similar sets of superposed spectra are formed on each side of the central image by the gratings, so that we may have two eye-holes if the distance between the spectra corresponds to the interocular distance.

It is interesting to consider that it is theoretically possible to produce one of these diffraction pictures directly in the camera on a single plate. If a photographic plate of fine grain were to be exposed in succession in the camera under red, green, and blue screens, on the surfaces of which diffraction gratings had been ruled or photographed, the plate on development should appear as a coloured positive when seen in the viewing apparatus. I have done this for a single colour, but the commercial plates are too coarse-grained to take the impression of more than a single set of lines. With specially made plates I hope to obtain better results.

R. W. WOOD.

## *LOCAL UNIVERSITY COLLEGES FOR LONDON.*

THE adequate provision of university education for London is by no means the simple and straightforward task which some people seem to imagine. From whichever of the many possible points of view the question of the education of London is considered, the anomalous position which has to be assigned to the greatest city in the world is the most noteworthy result of the investigation. If, for instance, an endeavour is made to estimate the comparative facilities offered for higher instruction in the metropolis with those to hand in other countries and in our own large provincial towns—judged on a basis of population—the results arrived at are as remarkable as they are interesting and instructive. The population of Scotland in 1896 was 4,186,849; yet located at Edinburgh, Glasgow, Aberdeen and St. Andrews are four well-equipped and largely endowed universities; while, in addition to these, is to be found at Dundee a college providing university education, and, though working with St. Andrews, in receipt of an annual grant of 1000*l.* from the Treasury. The population of the county of London was last year 4,504,766. If, as is done in the University of London Act, 1898, the towns within thirty miles of the university buildings are included, the population must be placed at a very much higher figure, viz. about six millions and three-quarters.

So that, keeping well within limits, and running no risk of any charge of exaggeration, the inhabitants of this metropolitan area may be said to considerably outnumber those of Scotland. When the universities and university colleges provided for this immense population are enumerated the total is ludicrously small. There is no teaching university, and but three university colleges—University College, King's College, and Bedford College. Of course, there are other colleges in London; but, in defining university colleges reference is made to the Treasury Minute of June 2, 1897, dealing with the grant in aid of the university colleges of Great Britain.

At University College there were in the faculties of Arts, Laws, and Science, in the session of 1895-6, 747 students, including engineering students. At King's College, during the same session, there were in Arts and Science 284 day students, 305 evening students, and 315 lady students. At Bedford College, the number of students throughout the same period numbered 176. The total number of persons receiving instruction of university standing in officially recognised institutions was consequently not much over 1500 during the year 1895-6.

If the populations up to date of the eight large towns in England provided with university colleges be added together, the total obtained is about 3,233,765. Similarly, Wales, with a population in 1891 of 1,501,163, has three university colleges, now together constituting the University of Wales. Not only in comparison with Scotland, therefore, but also by the side of Wales and the English provinces, London is seen to be extraordinarily deficient in properly authorised establishments the prime duty of which is to provide university instruction.

It may be urged at this stage that the work of the University of London Commission now being performed will, as it is intended it shall, completely alter the present unsatisfactory aspect of things, and that ere long provisions which will satisfy the most earnest advocate of higher education will be provided. But valuable as the coordination of effort which is likely to result from the inauguration of the new University of London will be, it can hardly be contended that to confer new powers upon certain existing colleges, and to rearrange the work of the staffs of institutions which have previously proved inadequate, will be a complete solution of the proper provision of university instruction for nearly seven millions of people.

It may be said at once that London should have a university college in each one of the various parts of the enormous district it covers. If one of the most important phases of the education imparted by the university is the intimate association of the undergraduate with his professors, the free exchange of views between the students themselves, and that mellowing effect which results from the feeling of a close connection with the corporate life of an important institution —then surely many small universities are incomparably better than one many-sided and multi-tentacled body with which the individual student can have no personal connection.

Nor is this conception of local universities in the different districts which build up the straggling wilderness we call London a dream of Utopia. As has been before pointed out in these columns, there already exist in London eleven polytechnic institutions, and the foundation stone of a twelfth has been laid. These, with four branches which have been established, provide sixteen separate centres scattered throughout an area which extends from Woolwich to Wandsworth in one direction, and from New Cross to Holloway in another. Why cannot some of these extensive buildings and lavishly furnished lecture-rooms and laboratories, representing half a million sterling in capital outlay, be utilised for the purpose of university work?

A reference to previous issues of NATURE will abundantly prove that there is nothing incongruous in undertaking university education in the lecture theatres, class-rooms and laboratories of these polytechnics. Comparatively few additions to the apparatus and fittings already provided would be necessary. Indeed, the work which has already been accomplished, valuable though it is, is scarcely return enough for the munificence of the City companies, the City parochial charities, the London County Council, private donors and others, which has placed the London polytechnics in their present condition of complete equipment.

A common retort to any such suggestion as has now been briefly stated—that the work of a university college is of a much more advanced nature than anything accomplished in a polytechnic—will not bear close examination. Several tests can easily be applied. An inspection of the lists of graduates of the London University, for instance, shows that a comparison of the numbers of successful candidates is all in favour of the polytechnics as compared with the university colleges. As it happens, it is possible to obtain the verdict of former professors of university colleges who are now engaged in the work of the polytechnics, and their assurance is that a greater quantity of advanced work, at all events in science, is done in the polytechnic. Moreover, the amount of work of an advanced type accomplished in English university colleges is usually somewhat exaggerated. A few quotations from a report presented in 1897 by Mr. P. H. Warren, President of Magdalen College, Oxford, and Prof. Liveing, Fellow of St. John's College, Cambridge, to the Lords Commissioners of her Majesty's Treasury, will justify this statement. Of one university college it is stated, "On the Arts side it cannot be said that at present any amount of work of a high standard is being done in the college," or later, "most of the work, both in arts and science, is of an elementary kind." Of another similar place of instruction, "With regard to the work now being done there, judged by University standards, a good deal of it is of an educational and preparatory rather than of an advanced and learned character." In the case of another college, "It is, therefore, not to be wondered at that the work on the Arts side should be still in a somewhat incipient stage, and mainly educational rather than learned." Of a fourth college it is reported, "A great deal of this work is in the nature of things of a somewhat preparatory kind, and there is throughout the college a great deal of work of not a very advanced character." Similar remarks concerning other university colleges might be multiplied, but quotations enough have been made to show that in apportioning the Treasury grant to university colleges the mere fact that elementary instruction is a part of the work carried on in the buildings is not considered a disqualification for also undertaking university instruction.

It is true that a very large part of the instruction of the 50,000 members and students enrolled by the London polytechnics takes place in the evening. This has been urged as evidence of the wide disparity between the methods of polytechnics and those of university colleges, but such an allegation reveals a want of knowledge of the prevalent conditions of instruction in university colleges. The evening classes of King's College, London, form an important part of the whole work of the institution. At Owens College, Manchester, a very complete system of evening lectures has been arranged for schoolmasters and others engaged during the day. The evening classes at University College, Liverpool, are strong and well attended, and are encouraged by the College authorities. The number of evening class students at Mason College, Birmingham, steadily increases. Besides the regular day work of the Bristol University College, there is an extensive system of evening classes, covering almost all the subjects taught in the college. At the Durham College of Science, Newcastle-upon-Tyne, there were in 1895-6, 1092 evening students compared with 499 day students. At Nottingham, in 1894-5, there were more than three evening students to one attending during the day.

Attention has already been called (No. 1523, p. 236) to the very complete arrangements in some of the polytechnics for instruction in the methods of scientific research, and to the excellent results, as evidenced by papers read to the learned societies, which have followed the lectures and demonstrations.

It would consequently appear that a judicious system of coordination and a little levelling-up would convert some of these sixteen institutions, which in the past ten years have had a phenomenal growth, and are steadily improving in status and influence, into satisfactory university colleges, bringing the highest order of culture to the very doors of the so-called metropolitan Philistines.

## *THE PLANS FOR ANTARCTIC EXPLORATION.*

IT is understood that the German Antarctic expedition for the year 1901 has now been fully organised. A grant of 60,000*l.* towards the expenses has been made by the Reichstag. Dr. Erich von Drygalski, one of the professors of geography in the University of Berlin, has been appointed the scientific leader, and an influential Committee is charged with perfecting the arrangements. This Committee is anxious that all the plans should be arranged for joint action, so that the German and British expeditions should supplement and reinforce one another at every point, thus ensuring the maximum return of scientific knowledge for the money expended. The expedition of the *Valdivia*, under the scientific leadership of Prof. Chun, is a proof of the splendid results which attend deep-sea expeditions under a scientific chief, if indeed the *Challenger* expedition did not supply proof enough. It is, however, still the opinion of some authorities in this country that an expedition which has to be carried in a ship must be under the sole and exclusive charge of a naval officer. The subject is one which

lends itself to discussion, and many illustrations may be adduced in favour of the arguments on either side.

It is gratifying to record that a national British expedition, well organised and excellently equipped, will be sent out to co-operate with the German expedition of 1901. That this expedition will be a purely scientific one is guaranteed by the fact that the organising body is a Joint-Committee of the Royal Society and the Royal Geographical Society, on which practical oceanographers and representatives of natural science are associated with the older generation of Arctic and Antarctic explorers. A responsible and representative directing body to which the choice of the leaders of the expedition can confidently be left is the first consideration, and this has been secured in the Joint-Committee. The first task of this Committee was to ascertain what resources would be available for carrying out the objects of the expedition. Three handsome contributions had been received—two of them from private individuals may indeed be termed magnificent—viz. 25,000*l*. from Mr. L. W. Longstaff, 5000*l*. from Mr. A. C. Harmsworth, and 5000*l*. from the Royal Geographical Society, while other subscriptions raised the total to 40,000*l*. Representations to the Government had produced no effect when the expedition was merely a project, but when Mr. Longstaff's donation made it certain that a British expedition would be equipped, Mr. Balfour, the First Lord of the Treasury, agreed to receive a deputation on the subject.

Accordingly, on June 22, a deputation waited upon Mr. Balfour at the Foreign Office, introduced by Sir Clements Markham, President of the Royal Geographical Society, and including Lord Kelvin, Sir Joseph Hooker, Sir Leopold McClintock, Sir Erasmus Ommanney, Dr. A. Buchan, Dr. R. H. Scott, Admiral Markham, Sir Vesey Hamilton, Sir W. White, Dr. Günther, Prof. Ray Lankester, Sir Michael Foster, Prof. Rücker, Prof. G. Darwin, Sir William Crookes, and a number of members of the Councils of the two Societies.

Sir Clements Markham, in introducing the deputation, laid great stress upon the scientific character of the proposed expedition. After bringing forward the historical argument of the interest taken by former Governments in polar exploration, and the value of navigation in those seas as a training for seamen and officers, he said (we quote the report in the *Times*):—

"Still the avowed object of Government expeditions was scientific research. The objects of the two societies were identical. They were undertaking work which successive generations of our statesmen and naval officers had looked upon as beneficial to the country and to the navy, and for this reason thought they had a claim on the Government for assistance. But further, some of the scientific results required were of immediate practical value. Indeed, all scientific research became eventually, directly or indirectly, practically useful. Much of the Antarctic work would, however, at once be of use to navigation, especially as regarded the magnetic survey."

Sir Joseph Hooker, the last survivor of the great Antarctic exploring voyage of the *Erebus* and *Terror*, under Sir James Ross, supported Sir Clements Markham, and Lord Kelvin followed with the hope that all would be done to bring the enterprise to a triumphant issue. Prof. Ray Lankester spoke of the importance of the biological observations, and especially referred to the question of a bi-polar fauna as one likely to be greatly elucidated by the expedition; and Prof. Rücker, in conclusion, pointed out how important the magnetic survey of the Antarctic area is.

Mr. Balfour replied in a sympathetic speech, in the course of which he said:—

"I, for my own part, fully recognise that if, as I think, expeditions to the poles of the earth, or towards the poles of the earth, are eminently desirable, both on practical and purely scientific grounds, these expeditions are perhaps even more important when undertaken towards the Antarctic Pole than towards the Arctic Pole, for we certainly know much less at present about the Antarctic regions than we do about the Arctic regions, and the actual area of this unknown but immense portion of the earth's surface is much larger in the case of the South Pole than in the case of the North Pole. . . . I, however, should not be representing my own personal convictions—and I am speaking in this matter for myself—if I for a moment let it be thought that in my judgment the scientific investigations which directly, immediately, and obviously lead to some practical result are the only ones which it is worthy of a great nation to pursue. I take a different view based partly upon the scientific experience of the world. If our forefathers of the last two centuries—I do not mean men of British origin alone, but I include the great French expeditions and other expeditions sent out during the last century and during the seventeenth century—had not carried on this work, it is manifest that our ignorance of the planet on which we live would be much more profound than it is at present; and it would not be creditable to an age which flatters itself, above all other ages, to be a scientific age, if without reluctance we acquiesced in the total ignorance which now envelops us of so enormous a portion of the southern hemisphere of our planet. For my own part, while I entirely agree with all that has been said upon the important facts and issues which may be anticipated from any expedition, I by no means limit my interest to such practical results. The things which we go directly to observe, and with every intention of observing, are doubtless of the highest importance. But I shall be greatly surprised if the expedition does not come across a great many phenomena which we did not expect, and which will throw a novel light upon many of the most important scientific theories, meteorological, geological, biological and magnetic. If this expedition is sent forth, as I hope it will be, adequately equipped at the date to our satisfaction, when we shall be able to co-operate with the German expedition, in respect of scientific interest alone such co-operation must be valuable from every point of view, and it will, among other things, have the effect of strengthening, if such strengthening be necessary or possible, the cosmopolitan or international character of these sciences. . . . I am sure if the Chancellor of the Exchequer were here to-day he would tell you that, in so far as he could meet the wishes of the deputation, such action on his part must be regarded not as a reason for giving something more to some future deputation, but rather as a reason for giving less. But with that caution, which I feel bound to utter on his behalf, I think I should not arouse undue hopes if I say that the Chancellor of the Exchequer will find it in his power to give substantially to the great project which you have in hand. I do not say that the aid given will reach the limits of your largest wishes, but I hope and believe that it will be sufficient to enable us to send out this expedition in a manner not unworthy either of the great societies which have interested themselves in this matter or of those liberal members of the public who have subscribed out of private means to further the object which you have in view, and not unworthy of the country which has done more than any other country in the past to send forth expeditions similar in character to the one which you desire to send forth."

Nothing could be more satisfactory than Mr. Balfour's view of the claims of research in pure science to public recognition, or his promise that a liberal grant to the Antarctic expedition shall be given by Government. It remains for the Joint-Committee to settle the plan of the expedition and to select the scientific leader on whose qualifications as a man of science and on whose freedom of action with regard to the executive authority of the ship or ships the success of the expedition as a scientific enterprise will entirely depend. This choice cannot be made too soon, for the details of scientific equipment must largely determine the plan of the ship which has to be built; and no one can be so well qualified to advise upon and carry out the preparations as the man whose reputation depends on the result of those scientific investigations which every one of the promoters of the expedition has declared to be its exclusive object.

## CHARLES WILLIAM BAILLIE.

We regret to have to announce the sudden death, at Broadstairs, on June 24, at the age of fifty-five years, of Naval Lieutenant Charles William Baillie, Marine Superintendent of the Meteorological Office, a post which he had held for eleven years.

Mr. Baillie was perhaps best known by his sounding machine, which he invented while on the North American Station about 1871, and which is still in use. It is a modification of the apparatus known as the "Hydra" machine. It was used in the *Challenger* expedition, and is described in Sir W. Thomson's book, "The Voyage of the *Challenger*." Lieut. Baillie was much employed in surveying, and while in the *Sylvia*, under Captain (now Vice-Admiral) St. John, on the China Station, he was selected by the Admiralty to be Director of Nautical Studies at the Imperial Naval College at Tokio, Japan. The results of his teaching are to be seen in the condition of the Japanese Navy at the present day.

After several years of duty in this important post he returned to England on half-pay. In October 1879 he joined the Meteorological Office, so that he had nearly completed twenty years of service in that institution.

The principal works which he has carried out there have been the charts of sea surface temperature, of barometrical pressure, and of currents for all oceans.

The discussion of the meteorology of the South Indian Ocean, from the Cape of Good Hope to New Zealand, which is shortly about to appear, has been carried out under Lieut. Baillie's superintendence, while he had laid down the lines of inquiry to be pursued in the work now n hand at the office—the "Meteorology of the South Atlantic and of the Coasts of South America." Lieut. Baillie was a Fellow of the Royal Geographical and the Royal Astronomical Societies. He married Miss Conyers, of Bermuda, and leaves a numerous family.

## NOTES.

Prof. W. C. Brögger, of the University of Christiania, has accepted an invitation to deliver the second course of the George Huntington Williams memorial lectures at the Johns Hopkins University, in April 1900. He has selected as his subject "Modern deductions regarding the origin of igneous rocks."

Dr. G. Agamennone has been selected to succeed the late Prof. M. S. de Rossi as director of the important Geodynamic Observatory at Rocca di Papa, near Rome. Dr. Agamennone, who is well known by his numerous seismological papers, has for several years been assistant at the Central Office of Meteorology and Geodynamics at Rome; and, during the years 1895–96, was in charge of the seismic department of the Meteorological Observatory at Constantinople.

News has been received of the death of Mr. John Whitehead while on a scientific mission in the Island of Hainan. Mr. Whitehead left England in the autumn of last year for the purpose of exploring the less known islands of the Philippine group and obtaining a collection of their fauna for the British Museum (Natural History).

We learn from *Science* that President McKinley has appointed a Commission to determine the best route for a canal across the Isthmus of Panama or Nicaragua. The sum of 1,000,000 dollars has been appropriated for the expenses of the Commission, and a number of surveyors will accompany the party which will shortly leave for Colon.

Dr. D. G. Brinton, Professor of American Archæology and Linguistics at the University of Pennsylvania, has presented to the University his entire collection of books and manuscript relating to the aboriginal languages of North and South America, representing the work of twenty-five years, and embracing about 2000 titles.

An excursion to Derbyshire, extending from August 3 to August 9, has been arranged by the Geologists' Association. The directors of the excursion are Mr. H. H. Arnold-Bemrose, Dr. Wheelton Hind, Mr. J. Shipman, and Mr. J. Barnes. A sketch of the geology of the Lower Carboniferous rocks of Derbyshire will be given by Mr. Arnold-Bemrose at a meeting of the Association on July 7.

The preliminary programme of the thirteenth International Medical Congress, to be held in Paris from August 2 to August 9, 1900, has just been issued from the central offices in the Rue de l'École de Médecine. M. Lannelongue is president of the Congress, and Dr. Chauffard is the secretary-general. National Committees have been formed in each country to further the work of the Congress. The president of the Committee for Great Britain is Sir William MacCormac, Bart., K.C.V.O., and the hon. secretaries are Dr. Garrod, Dr. Keser, and Mr. D'Arcy Power.

The second trade exhibition of photographic and scientific apparatus and sundries will be held in the Portman Rooms, on April 27 to May 5 next year. Intending exhibitors should communicate with the Secretary of the Exhibition, 15 Harp Alley, Farringdon Street, E.C.

To celebrate the centenary of the granting of the charter to the Royal College of Surgeons of England in 1800, the Council propose to apply for a supplementary charter. It is proposed to obtain powers to confer the Fellowship of the College on persons of distinction who are not members. A memorial has been drawn up, suggesting to the Council that a favourable opportunity now presents itself for the satisfaction of that desire which has at various periods during the century, and especially during the last fifteen years, been expressed by a large number of the members of the College—viz. that they should be represented on the Council. It is submitted that "it would be both equitable and politic that the members should have a voice in the conduct of a Corporation of which they are, and always have been, numerically and financially the mainstay." At every annual meeting of Fellows and members (instituted in 1884) this or some similar proposal has been carried practically unanimously, and a petition in its favour was signed by nearly 5000 members and presented to the Privy Council. The Council have twice taken a poll of the Fellows on the question, but on neither occasion has an absolute majority voted against the proposal, though many were in its favour.

The *Academy* invited its readers to compose an inscription, of not more than forty words, suitable to be engraved upon the statue of Charles Darwin, just unveiled at Oxford. The best inscription was considered to be that submitted by Mr. Edwin Cardross, viz.: "Charles Darwin, the great naturalist, memorable for his demonstration of the law of evolution in organic life, achieved by scientific imagination, untiring observation, comparison, and research: also for a blameless life, characterised by the modesty, 'the angelic patience, of genius.'"

An interesting survival of the very ancient custom of watching the sun rise at the summer solstice was witnessed on Salisbury Plain on June 21. The *Westminster Gazette* states that on the night preceding the longest day (June 21) there was a large gathering of people from the neighbourhood, and also from other parts, assembled close to the historic circle of stones at Stonehenge, in order to see the sun rise over the Plain. When atmospheric conditions are favourable, those watching

rom the altar stone in the centre of the circle see the sun apparently poise itself for an instant upon the top of the stone known as the Friar's Heel. This sight is a rare privilege, and as it depends upon a doubtful meteorological condition—a perfectly cloudless sky at the point and time at which the sun rises above the horizon—those watching anxiously scan the sky, alas ! in too many instances, to find that their night's vigil on the Plain is barren of result. The last time the phenomenon was witnessed was in 1895.

THE annual general meeting of the Jenner Institute of Preventive Medicine was held at Chelsea on June 23. The report of the Council for the year was read and adopted. The report states that during the year the work of the institute continued to make satisfactory progress. The internal fittings of the Chelsea building are now completed with the exception of the museum, and the various departments are fully equipped and at work. The meeting received with enthusiasm the reference to Lord Iveagh's gift of 250,000*l.* for the promotion of the objects for which the institute was founded. The gratifying announcement was made that Lord Lister had consented to act as chairman of the new governing body that will in future control the affairs of the institute. Dr. Macfadyen's report upon the general work of the institute during the year was read and adopted. During the year the organisation of work in the main laboratories of the institute was completed, and valuable additions made to the stock of scientific apparatus. The foundations of the new wing, which will complete the original plan of the institute, are at present in course of construction. The photographic department is fully equipped, and the necessary illustrations to scientific papers will in future be prepared in this laboratory. At no period has there been a greater body of research work in progress in the institute than at the present moment, and reference is made in the report to the more important investigations being carried on. A number of investigations by Dr. Hewlett and others have been published during the year, and a second volume of the *Transactions* of the institute is going through the press. As regards the courses of instruction, which have been well attended, the aim has been to train the advanced student, as is done in foreign laboratories, with a view to subsequent research work. A notable addition has been made to the departments of the institute by the foundation of the Hansen Laboratory for the study of the practical application of bacteriology to industrial and technical processes. Dr. G. Harris Morris has been placed in charge of this department, which is now at work. Dr. A. Harden's report deals with the work of the chemical and water laboratory during the year. Dr. G. Dean's report on the antitoxin department describes the improved methods adopted for the preparation of diphtheria anti-toxin and the researches being carried out in connection with tetanus, pneumonia, anti-streptococcic serum, &c.

AT the suggestion of Prof. E. Ray Lankester, Lieut. A. G. Froud has sent us a copy of a report, by Mr. G. T. Prior, upon some fine brown dust collected on board the P. and O. s.s. *Sumatra* during a thunderstorm in the Galita Channel, Mediterranean. The dust contained about 33 per cent. of doubly refractive grains, composed chiefly of carbonates of calcium, magnesium, and iron. After treatment with hydrochloric acid, the insoluble residue was for the most part without influence on polarised light, and consisted mainly of silicate of alumina (clay), with a little organic matter ; only a few angular grains of quartz, and one or two very strongly refractive and doubly refractive grains, probably of iron, were observed in this insoluble residue. The dust was thus of the nature of an argillaceous and calcareous sand, and may have been carried by wind from the north of Africa. In his report, Mr. Prior remarks :—"An account by C. V. John, with analysis of fine brown dust which fell in Hungary in February 1896, will be found in *Verh. Geol. Reichsanst.* (ix., 1896, pp. 259-64). This dust, like the above, was characterised by the almost total absence of quartz, and by the presence of grains of transparent amorphous clay material. It differed from the above, however, in not containing any large amount of carbonates. The similarity in chemical composition of this Hungarian dust with that of Nile mud is pointed out, and the suggestion is made that the dust may have been derived from Egypt."

DR. MOTTE, naturalist, 13 rue Royale, Lyons, informs us that the family of a deceased collector have an egg of the Great Auk (*Alca impennis*) among other ornithological objects they desire to sell.

A FEW interesting facts with regard to the kea, or sheep-eating parrot, of New Zealand are related in the July number of the *Leisure Hour* by Dr. F. Truby King. The intense curiosity of these birds is stated to be sufficient to account for the habit of eating sheep acquired by them. Dr. King thinks it is probably a mistake to suppose that the kea designedly makes at once for the kidney fat of the sheep upon which it has pounced. It eats into various parts of the body, though perhaps more often into the region of the kidney, as it is there that the kea gets the firmest stand on the back of the running sheep. This view is strengthened by the fact that the bird prefers double-fleeced sheep—that is, such as have remained a whole season unshorn, on which it obtains a firmer grip.

IN an article on the Gold Measures of Nova Scotia (Canadian Mining Inst., March), Mr. E. R. Faribault remarks that the workable deposits of free gold are confined to the metamorphic rocks of the Atlantic coast, and occupy an area of about 5000 square miles. The gold-bearing rocks are intersected by dykes and large masses of granite which have no connection with the auriferous veins. It is observed, however, that all the rich veins and the large bodies of low grade quartz, with few exceptions, follow the planes of stratification, and occur at well-defined points along the anticlinal axes of the folds. The rocks are regarded as of Lower Cambrian age.

DR. HEPITES, director of the Meteorological Institute of Roumania, has communicated to *Ciel et Terre* of March 1 an interesting summary of the climatology of the Roumanian coast of the Black Sea. Thanks to the observations persistently made by the European Commission of the Danube, there is an uninterrupted series of observations for twenty-two years at Soulina and another series of thirteen years at Constantza, made under the superintendence of the institute. The temperature of the air at both these places is nearly similar ; the yearly mean at the latter place is 51°·8. The highest shade temperature was 97°·2 in July, and the lowest −5°·3 in January. The extreme temperatures recorded in other parts of Roumania are 108° at Giurgevo in July 1896, and −32°·1 in January 1893. The rainfall on the coast is comparatively small, the average annual amount at Constantza is 15·7 inches. It is very seldom that the rainfall in any one year exceeds 20 inches ; at Soulina during the last thirty years it has twice exceeded 23 inches. Rain falls on an average on 76 days in the year, and is spread fairly equally throughout all the months ; snow falls on an average during 12 days in the year.

THE thirteenth volume (for 1897) of the *Analele* of the Meteorological Institute of Roumania has recently been published. In his annual report, the director, Dr. S. C. Hepites, who is now retiring after thirty years of service to the State, gives a history of the meteorological service during the first thirteen years of its working. In 1883 there were only three

meteorological, and ten pluviometric, stations in the whole country. There are now a meteorological station of the first order at Bucharest, thirty-eight of the second order, one of the third, and 327 pluviometric stations within an area of 131,400 sq. km. The annual volume, which in the present case contains nearly 800 quarto pages, bears testimony to the value of the work accomplished. Besides the usual meteorological tables, it contains an account of the new magnetic observatory at Bucharest by M. St. Murat, and nine other memoirs, among which may be mentioned those by the director on rain at Bucharest during the last thirty-two years, the rainfall of Roumania in 1897, the magnetic elements of Bucharest, and on the register of earthquakes, eleven in number, felt during the year 1897.

IN the columns of NATURE last autumn, attention was directed by several writers to the phenomenon well known amongst iron-workers that if a bar of steel or iron, heated to a red or white heat at one end, have that end suddenly plunged into cold water, the other end will appear to become hotter. Prof. E. Lagrange, writing in the *Bulletin* of the Belgian Academy (1899, No. 4), describes experiments showing that this effect is quite compatible with the ordinary laws of conduction of heat. The bar in every case is removed from the fire before the stationary point has been reached; the temperature of the unheated end is increasing at the time of removal, and as its rate of change does not vary discontinuously, it continues to increase after removal. When the hot end of the bar is suddenly cooled, Prof. Lagrange finds that the other end attains its maximum temperature sooner, and this maximum is considerably lower than when the hot end is cooled slowly. If, however, the bar is heated until the flow of heat has become steady, no further increase takes place at the other end, whether the hot end is cooled slowly or suddenly, but the unheated end begins to cool at once, and its cooling is more rapid in the second than in the first case.

WHETHER corresponding to the Zeeman effect there exists the reciprocal phenomenon of the production of a magnetic field by a circularly polarised ray has been discussed by Profs. Fitzgerald and Gray in NATURE for January 5 and February 16. Prof. Augusto Righi, writing in the *Atti dei Lincei*, viii. (1), 7, describes his own experiments on the subject. Prof. Righi used columns of vapour of hypo-azotide and of bromine, the illumination being produced by a plane polarised beam of sunlight, between which and the tube two quarter-wave laminæ of quartz oppositely turned were placed. An astatic magnetometer showed no deviation either when the sense of polarisation was reversed by interchanging the quartzes or when the light was cut off, although a magnetic field of $10^{-6}$ C.G.S. units produced a perceptible deviation. In another note, published in the *Rendiconto* of the Bologna Academy, Prof. Righi describes his determination of the rotatory power of chlorine in a magnetic field. The numerical measure of this effect referred to bisulphide of carbon was found to be 0·000337, and chlorine is thus intermediate between carbonic anhydride and protoxide of nitrogen, whose rotatory powers, as found by Becquerel, are 0·000302 and 0·000393 respectively.

FROM a paper published by Drs. Rabinowitsch and Kempner in the *Zeitschrift für Hygiene* on the milk of tuberculous cows, the chance of infection from the latter appears to be greater than was even supposed. Whereas it has been generally found that cow's milk only contains tubercle bacilli when the udder is affected, or when the animal is in an advanced stage of tuberculosis, the above authors have found the bacilli in milk in the very beginnings of the disease, and without any udder affection, as well as in latent cases where its existence could only be verified by the tuberculin test. The authors point out that it is not sufficient to make one examination only of the milk, and they cite an instance in which, whilst the milk gave a negative result, butter made from the milk derived from the same cow on the same day on inoculation into guinea-pigs resulted in the death of the latter from tuberculosis, whilst an examination of this cow's milk made at a later date revealed the presence of tubercle bacilli. In view of these investigations, the authors are of opinion that the milk of all cows which react to the tuberculin test ought to be regarded with suspicion, and they point out, moreover, the great value which attaches to this test in helping to obtain milk-supplies free from the contagion of tuberculosis.

IT is always with pleasure that we receive a new *Bulletin* o the Madras Government Museum, as we are sure to find therein brightly written and instructive papers on the native races of Southern India by Mr. Edgar Thurston, the superintendent of the Museum. The most important of these little memoirs in the last issue (vol. ii. No. 3) is one on the Kadirs of the Anaimalai Hills. They are a dark-skinned, curly-haired people, short in stature (average 1·577) with a broad span (1·688), deep-chested, and like many mountaineers they rarely walk with a straight leg. The head is narrow (average 72·9), the jaws do not project, and the nose is wide (average 89·8). They thus are good representatives of the ancient population of Southern India. They have one remarkable custom which appears to be unique in the Indian peninsula, and that is the chipping of all or of some of the incisor teeth of both jaws into the form of a sharp-pointed cone.

IN a note on the Dravidian head, Mr. Thurston (*loc. cit.*) states that the average cephalic index of 639 Dravidians belonging to nineteen tribes and castes is 74·1. Out of the total number measured by him only nineteen, or 3 per cent., of the indices exceeded 80, the maximum being 83·7. In a discussion on the Dravidian problem, Mr. Thurston gives only a few original observations, and has collected the opinions of a number of authors, but he does not sum up or give us his own conclusions.

THE origin of life, as developed from a mechanical foundation, forms the subject of a work by Dr. Ludwig Zehnder, of Freiburg, the first part of which has just reached us. After referring to the work of Darwin and his successors, the author tells us in his introduction that there has long been a hope that a direct transition between unorganised and organised bodies would some day be discovered, but that hitherto the gap has not been bridged. Apparently it is his intention to show how the two great groups are at present known to approach one another. The present part treats of Monads, simple cells, and Protistæ.

IN broad contrast to the foregoing may be mentioned a brief paper by M. E. Lefort, published at Lyons under the title of "Fausseté de l'Idée Evolutioniste appliquée au Système Planétaire ou aux Espèces Organiques." The general contention appears to be that every change in nature is due to direct Divine interposition.

A SHORT account of the first voyage of the Prince of Monaco's new vessel, *Princess Alice II.*, appears in the *Comptes rendus*; and a fuller description of the work in northern waters, illustrated by photographs, is published in the Paris *Bulletin du Muséum d'histoire naturelle*. The expedition of last year started from Havre in June, and, after a meeting with the Emperor of Germany off the Norwegian coast, worked in Spitsbergen waters till the end of August, returning to Havre about the middle of September. Extended physical and biological observations were made both at sea and on a number of islands in high northern latitudes. The collections

will be added to the museum of oceanography recently founded by the Prince at Monaco.

WE have received the first number of *Finland*, an "English journal devoted to the cause of the Finnish people."

*Science* of June 16 publishes a translation of a criticism of the plans for an International Catalogue of Scientific Literature, contributed to the *Zoologische Anzeiger* by Prof. J. Victor Carus.

A MEETING of the Anatomical Society of Great Britain and Ireland will be held in the Anatomical Schools, New Museums, Cambridge, on Saturday, July 8, commencing at 2 p.m.

MESSRS. J. AND A. CHURCHILL announce that they will shortly publish the following scientific works: A text-book of physics by Prof. Andrew Gray, F.R.S.; the book will be issued in three parts, the first to appear being that on dynamics and properties of matter. A work on medical electricity for the use of students and practitioners, by Dr. W. S. Hedley. A handbook on chemistry and physics, for students preparing for the first examination of the Conjoint Board, by Messrs. Corbin and Stewart.

THE additions to the Zoological Society's Gardens during the past week include a Rhesus Monkey (*Macacus rhesus*, ♀) from India, presented by Mrs. L. Smallcombe; a Macaque Monkey (*Macacus cynomolgus*) from India, presented by Mr. J. H. Johnston; a Diana Monkey (*Cercopithecus diana*, ♀) from West Africa, presented by Mr. T. N. Loy; a —— Deer (*Cariacus*, sp. inc. ♂) from Tobago, presented by Captain J. Leslie Burr, R.N.; a Stone Curlew (*Aedicnemus scolopax*), European, presented by Mr. D. T. Campbell; six Cormorants (*Phalacrocorax carbo*, juv.) from Scotland, presented by Mr. Percy Leigh Pemberton; a Yellow-crowned Penguin (*Eudyptes antipodum*), a Thick-billed Penguin (*Eudyptes pachyrhynchus*) from New Zealand, a Rock-hopper Penguin (*Eudyptes chrysocome*) from the Falkland Islands; two Elephantine Tortoises (*Testudo elephantina*) from the Aldabra Islands, a Reticulated Python (*Python reticulatus*) from the East Indies, deposited; a Red Deer (*Cervus elaphus*, ♂), born in the Gardens; two Coscoroba Swans (*Coscoroba candida*) from Antarctic America, purchased.

## *OUR ASTRONOMICAL COLUMN.*

ASTRONOMICAL OCCURRENCES IN JULY:—

July 2. 9h. 16m. to 11h. 14m. Transit of Jupiter's Sat. III.
3. 12h. 40m to 13h. 30m. Occultation of the star D.M. + 21°, 539 (mag. 5·7) by the moon.
3. 14h. 57m. to 15h. 43m. Occultation of the star 32 Tauri (mag. 5·7) by the moon.
5. 15h. Conjunction of Venus and the moon (♀ 1° 0′ south).
6. 10h. Conjunction of Venus and Neptune (♀ 0° 46′ north).
13. 9h. 51m. Minimum of Algol (β Persei).
15. Venus. Illuminated portion of disc 0·955, Mars 0·931.
19. 8h. 6m. to 9h. 17m. Occultation of B.A.C. 5709 (mag. 6·3) by the moon.
19. 8h. 9m. to 9h. 24m. Occultation of 26 Ophiuchi (mag. 6·1) by the moon.
19. 14h. Conjunction of Saturn and the moon (♄ 2° 26′ north).
20. 7h. 39m. to 8h. 41m. Occultation of 7 Sagittarii (mag. 5·4) by the moon.
20. 8h. 4m. to 9h. 15m. Occultation of 9 Sagittarii (mag. 5·7) by the moon.
21. 23h. Mercury at greatest elongation (26° 59′ east).
24. 9h. 26m. Jupiter's Sat. IV. in conjunction with north pole of planet.
28. Tempel's comet (1873 II.) in perihelion.

TEMPEL'S COMET 1899 *c* (1873 II.)—The following ephemeris is contributed to the *Astr. Nach.* (Bd. 149, No. 3574), by M. L. Schulhof.

*Ephemeris for 12h. Paris Mean Time.*

| 1899. | R.A. h. m. s. | Decl. ° ′ ″ | Br. |
|---|---|---|---|
| June 29 ... | 20 13 33·4 ... | − 8 35 52 ... | 2·525 |
| 30 ... | 14 51·3 ... | 8 56 1 | |
| July 1 ... | 16 8·8 ... | 9 16 56 | |
| 2 ... | 17 25·9 ... | 9 38 37 | |
| 3 ... | 18 42·5 ... | 10 1 5 ... | 2·770 |
| 4 ... | 19 58·6 ... | 10 24 18 | |

| 6 ... | 20 22 29·7 ... | −11 13 0 | |

FIFTH SATELLITE OF JUPITER.—In *Bulletin* No. 10 of the Yerkes Observatory (*Astrophysical Journal*, vol. ix., p. 358), Prof. G. E. Hale gives the measures of Jupiter's fifth satellite which have recently been made by Prof. E. E. Barnard with the 40-inch refractor. The observations were made on five nights during March and April 1898, and on four nights during April and May 1899. The constants determined are as follows:—

| Times of east elongation, G.M.T. d. h. m. | East elongation distance. ″ |
|---|---|
| 1898 March 2 18 57·80 ... | ... ... |
| 1898 March 6 18 36·11 ... | ... ... 48·14 |
| 1898 April 5 ... ... | ... ... 48·12 |
| 1899 April 25 19 5·26 ... | ... ... 48·34 |
| 1899 May 1 18 32·72 ... | ... ... 48·29 |

The different values of the elongation distance are due to the revolution of the line of apsides, which, as Tisserand showed, takes place in a period of five months. The consistency of the measures with the instrument are shown by the plotted curve of the 131 observations of May 1, none of which depart more than 0″·4 of arc from the mean.

The great number of revolutions made by the satellite since its discovery in 1892 render possible an accurate calculation of its period. Using the elongations of September 10, 1892, March 6, 1898, April 25, 1899, and May 1, 1899, the resulting periodic time is found to be

11h. 57m. 22·647s.

OXFORD UNIVERSITY OBSERVATORY.—The twenty-fourth annual report of the Savilian Professor contains an account of the work accomplished from June 1, 1898, to May 31, 1899, and a survey of the condition of the instrumental equipment. The large dome, erected in 1875, has become so defective that plans for a new one have been prepared, the estimated cost being 440*l*. In consequence of disadvantages resulting from the unprotected state of the observatory, the need of a residence is strongly urged. During the year the observatory has been greatly enriched by the acquisition of the library of the late Mr. George Knott. Among the numerous presents received, special mention is made of a long series of early nautical almanacs, extending from 1767 to 1843, kindly given by Mr. Robert Gordon.

The De la Rue astrographic telescope is in good order, 258 plates for the catalogue having been taken during the year. The De la Rue reflector and the Barclay transit circle are both in good order. With the latter an unknown, variable change of collimation error has been traced to the looseness of the object-glass in its cell, this being finally eliminated by cotton wool packing.

No time has been found to proceed further with the photographic transit circle. The four micrometers for measuring the catalogue plates are in general use, one being in charge of Mr. T. J. Moore, of Doncaster, who has measured 61,186 stars with it.

The staple work of the observatory staff has been the measurement and reduction of the plates for the astrographic catalogue, and about half of this is now done, 586 plates out of the 1180 allotted to the observatory having been measured, and 525 completely reduced. In the region of the Milky Way the times of exposure for the plates have been reduced to 3 min., 1 min. and 20 secs., the number of stars even with the smaller exposure being still over 300.

Considerable interest attaches to the investigation undertaken to determine the possible distortion present in a large photographic doublet. Positives from plates taken with the 24-inch Bruce doublet at Arequipa have been lent by Prof. Pickering,

and the results of their examination prove that it is possible to get large fields sensibly free from optical distortion. This has a most important bearing on the carrying out of the "chart" work, as it is at present necessary to expose for one hour to obtain a region $2^{\circ} \times 2^{\circ}$, whereas the new form of lens would give a much larger region in the same time. For this reason, Prof. Turner has indefinitely postponed the taking of the "chart" plates for the Astrographic Survey.

Cambridge Observatory.—Embodied in the *Cambridge University Reporter* for June 16, is the annual report of the Cambridge Observatory from 1898 May 26 to 1899 May 25. With the meridian circle, 2241 observations of 1420 stars have been taken, most of these being repetitions of previous observations for the catalogue.

One hundred and seventy-six observations have been made of the Harrow occultation stars; and, at the request of Dr. Gill, observations of heliometer comparison stars were commenced in March and are still in progress.

In addition, there have been other measurements of standard stars, bringing up the total number of meridian observations to 3616.

The new bent equatorial, to be called the "Sheepshanks equatorial" (see illustrated description in *Monthly Notices*, R.A.S., 1899 January, vol. lix. p. 152) was completed about September 1898, and its adjustment was undertaken by Mr. Hinks. It was soon found that the objective tube had a large flexure, and a new tube is being made. The first trial photographs were unsatisfactory, the disturbing cause being thought to be the air currents in the tube, which is partly open near the joint.

The Newall telescope has been employed on 96 nights during the year, in connection with the Bruce spectroscope, in taking photographs of stellar spectra for determining their velocity in the line of sight; 150 photographs have been obtained, giving material for determining the velocity of 60 stars. Thirty of these are included in the Potsdam list of 51 stars observed from 1888-1891. Preparations are in hand for converting the spectroscope into a powerful 4-prism instrument for detailed examination of a few of the brightest stars. Special series of stellar spectra have been taken to assist in the reduction of the eclipse photographs obtained in India in 1898. For this purpose also attempts have been made to separate scandium salts from the mineral gadolinite.

## *PICTURES PRODUCED ON PHOTOGRAPHIC PLATES IN THE DARK.*[1]

I think I may fairly assume that every one in this theatre has had their photograph taken, and consequently must have some idea of the nature of the process employed. I have, therefore, only to add, with regard to what is not visible in the process of taking the picture, that the photographic plate is a piece of glass or such like body, coated on one side by an adhesive paste which is acted on by light, and acted on in a very remarkable manner. No visible change is produced, and the picture might remain latent for years, but place this acted on plate in a solution, of, say pyrogallol, and the picture appears. The subsequent treatment of the plate with sodium hyposulphite is for another purpose, simply to prevent the continuance of the action when the plate is brought into the light. Now, what I purpose demonstrating to you to-night is that there are other ways of producing pictures on photographic plates than by acting on them by light, and that by these other means a latent picture is formed, which is rendered visible in precisely the same way as the light pictures are.

The substances which produce on a photographic plate these results, so strongly resembling those produced by light, are, some of them, metallic, while others are of vegetable origin. At first it seemed very remarkable that bodies so different in character should act in the same way on the photographic plate. The following metals—magnesium, cadmium, zinc, nickel, aluminium, lead, bismuth, tin, cobalt, antimony—are all capable of acting on a photographic plate. Magnesium most strongly, antimony but feebly, and other metals can also act in the same way, but only to a very slight extent. The action in general is much slower than that of light, but under favourable conditions a picture may be produced in two or three seconds.

[1] A lecture delivered at the Royal Institution on Friday, May 5, by Dr. W. J. Russell, V.P.R.S.

Zinc is nearly as active as magnesium or cadmium, and is the most convenient metal to experiment with. In its ordinary dull state it is entirely without the power of acting on a photographic plate, but scratch it or scrape it, and it is easy to prove that the bright metal is active. I would say that all the pictures which I have to show you, by means of the lantern, are produced by the direct action of the metal, or whatever the active body may be, on the photographic plate, and that they have not been intensified or touched up in any way. This first slide is the picture given by a piece of ordinary zinc which has been rubbed with some coarse sand paper, and you see the picture of every scratch. Here is a piece of dull zinc on which some circles have been turned. It was exposed to the photographic plate for four hours at a temperature of 55° C. In the other cases, which are on a larger scale, a zinc stencil was polished and laid upon a photographic plate, and you see where the zinc was in contact with the plate much action has occurred. In the other case a bright zinc plate was used, and a Japanese stencil interposed between it and the photographic plate, and a very strong and sharp picture is the result. The time required to produce these zinc pictures varies very much with the temperature. At ordinary temperature the exposure would have to be for about two days, but if the temperature was, say, 55° C., then half to three-quarters of an hour might be sufficient. Temperatures higher than this cannot be used except for very short times, as the photographic plate would be damaged. Contact between the zinc and photographic plate is not necessary, as the action readily takes place through considerable distances. Obviously, however, as you increase the distance between object and plate, so you decrease the sharpness of the picture, as is shown by the following pictures, which were taken respectively at a distance of 1 mm. and 3 mm. from the scratched zinc surface. The appearance of the surfaces of different metals varies, and the following slides show the surface of a plate of bismuth, a plate of lead, and one of aluminium. On the next slide are the pictures produced by similar pieces of pure nickel and cobalt, and it clearly shows how much more active in this way nickel is than cobalt. Many alloys, such as pewter, fusible metal, brass, &c., are active bodies, and in the case of brass the amount of action which occurs is determined by the amount of zinc present. Thus you will see that a brass with 30 per cent. of zinc produces hardly any action on the photographic plate, but when 50 per cent. of zinc is present there is a fairly dark picture, and when as much as 70 per cent. is present a still darker picture is produced. The second class of bodies which act in the same way on a photographic plate are organic substances, and belong essentially to the groups of bodies known as terpenes. In trying to stop the action of metallic zinc, which I thought at the time might arise from vapour given off by the metal, copal varnish was used, but in place of stopping the action it was found to increase it, and this increase of activity was traced to the turpentine contained in the varnish. In experimenting with liquids it is convenient to use small shallow circular glass vessels such as are made for bacteriological experiments, the plate resting on the top of the vessel, and the amount of liquid in the vessel determining the distance through which the action shall take place. The following slide, produced in this way, shows how dark a picture ordinary turpentine produces. All the terpenes are active bodies. Dipentine is remarkably so; in a very short time it gives a black picture, and if the action be continued, the dark picture passes away, and you then have a phenomenon corresponding to what photographers call reversal. The strong smelling bodies known as essential oils, such as oil of bergamot, oil of lavender, oil of peppermint, oil of lemons, &c., are all active bodies, and all are known to contain in varying quantities different terpenes; therefore ordinary scents are active bodies, and this is shown by the following pictures produced by eau de Cologne, by cinnamon, by coffee, and by tea. Certain wines also act in the same way, Sauterne gives a tolerably dark picture, but brandy only a faint one. Other oils than these essential ones are also active bodies; linseed oil is especially so; olive oil is active, but not nearly as much so as linseed oil; and mineral oils, such as paraffin oil, are without action on the photographic plate.

Interesting results are obtained with bodies which contain some of these active substances; for instance, wood will give its own picture, as is shown by the following slides: the first is a section of a young spruce tree, the next a piece of ordinary deal, and the third of an old piece of mahogany. Again, the

next slide you will recognise as the picture of a peacock's feather. There is much interest in these pictures of feathers, as they distinguish the brilliant interference colours from those produced by certain pigments; the beautiful blue in the eye of the peacock's feather is without action on the photographic plate. Butterflies' wings, at least some of them, will draw, as you see, their own pictures. Linseed oil, which is a constituent of all printing ink, makes it an active body, and it can, like the zinc and other active bodies, act through considerable distances. In the picture before you the ink was at a distance of one inch from the plate, and the next slide shows what a remarkably clear and dark picture ordinary printing can produce. As the composition of printing ink varies so does its activity, and here are pieces of three different newspapers which have acted under the same conditions on the same plate, and you see how different the pictures are in intensity. Printed pictures, of course, act in the same way; here is a likeness of Sir H. Tate taken from "The Year's Art." The pictures and printing in *Punch* always print well, so does the yellow ticket for the Friday evening lectures at the Royal Institution; also the rude trade-mark on Wills's tobacco, and it is of interest because the red pigment produces a very clear picture, but the blue printing is without action on the plate.

An interesting and important peculiarity of all these actions is that it is able to pass through certain media; for instance, through a thin sheet of gelatin. Here are two plates of zinc; both have been scratched by sand-paper; one is laid directly on the photographic plate, and the other one has a sheet of gelatin, its colour is of no note, laid between it and the sensitive plate; the picture in this case is, of course, not so sharp as when no gelatin is present, but it is a good and clear likeness of the scratches.

Celluloid is also a body which allows the action to pass through it, as is seen in this picture of a piece of perforated zinc, a picture which was produced at ordinary temperatures. Gold-beaters' skin, albumen, collodion, gutta-percha, are also bodies which are transparent to the action of the zinc and the other active bodies. On the other hand, many bodies do not allow the transmission of the action through them; for instance, paraffin does not, and among common substances writing ink does not, as is easily shown by placing ordinary paper with writing on it between the active body and the photographic plate. The active body may conveniently be either a plate of zinc or a card painted with copal varnish and allowed to dry, or a dish of drying oil. The picture of an ordinarily directed envelope shows this opacity of ink well. It is a property long retained by the ink, as this picture of the direction of a letter, written in 1801, shows; also this letter of Dr. Priestley's, dated 1795, and here is also some very faded writing of 1810, which still gives a very good and clear picture. Even if the writing be on parchment, the action passes through the parchment, but not through the ink, and hence a picture is formed.

With bodies which are porous, such as most papers, for instance, the action passes gradually through the interstices, and impresses the plate with a picture of the general structure of the intervening substance. For instance, the following pictures show the structure and the water-mark of certain old and modern writing papers. Some modern writing papers are, however, quite opaque; but usually paper allows the action to take place through it, and combining this fact with the fact of the strong activity of the printing ink, the apparently confused appearance produced on obtaining a picture from paper with printing on both sides is accounted for, as the printing on the side away from the photographic plate, as well as that next to it, prints through the paper, and is, of course, reversed.

I hope I have now given you a clear idea how a picture can be produced on a photographic plate in the dark, and the general character and appearance of such pictures. I now pass on to the important question of how they are produced. Moser suggested fifty years ago that there was "dark light," which gave rise to pictures on polished metallic plates, and lately it was suggested that pictures were produced by vapour given off by the metals themselves; the explanation, however, which I have to offer you is, I think, simpler than either of these views, for I believe that the action on the photographic plate is due to the formation of a well-known chemical compound, hydrogen peroxide, which undergoing decomposition acts upon the plate and is the immediate cause of the pictures formed. The complicated changes which take place on the sensitive plate I have nothing to say about on the present occasion, but I desire to convince you that this body, hydrogen peroxide, is the direct cause of these pictures produced in the dark. Indirect proof has to be resorted to. Water cannot be entirely excluded, for an absolutely dry photographic plate would probably be perfectly inactive, and as long as water is present peroxide of hydrogen may be there also. But what are the conditions under which these pictures are formed? Only certain metals are capable of producing them. This list of active metals which I have mentioned to you was determined solely by experiment, and when completed it was not evident what common property bound them together. Now, however, the explanation has come, for these are the very metals which most readily cause, when exposed to air and moisture, the formation of this body, peroxide of hydrogen. Schönbein showed as long ago as 1860 that when zinc turnings were shaken up in a bottle with a little water hydrogen peroxide was formed, and the delicate tests which we now know for this body show that all the metals I named to you not only can in the presence of moisture produce it, but that their power of doing so follows the same order as their power of acting on a photographic plate. Again, what happened with regard to the organic bodies which act on the photographic plates? I have already mentioned that in experimenting with the metals it was accidentally observed that copal varnish was an active substance producing a picture like that produced by zinc, and that the action was traced to the turpentine present; again, a process very much like groping in the dark had to be carried on in order to determine which were active and which inactive organic bodies, and the result obtained was that the active substances essentially belonged to the class of bodies known to chemists as terpenes. Now a most characteristic property of this class of bodies is that in presence of moisture and air they cause the formation of hydrogen peroxide, so that whether a metal or an organic body be used to produce a picture, it is in both cases a body capable, under the circumstances, of causing the formation of hydrogen peroxide. Passing now to experimental facts, which confirm this view of the action on sensitive plates, I may at once say that every result obtained by a metal or by an organic body can be exactly imitated by using the peroxide itself. It is a body now made in considerably quantity, and sold in solution in water. Even when in a very dilute condition it is extremely active. One part of the peroxide diluted with a million parts of water is capable of giving a picture. It can, of course, be used in the glass dishes like any other liquid, but it is often convenient not to have so much water present; and then it is best to take white blotting-paper, wet it in the solution of the peroxide, and let it dry in the air. The paper remains active for about twenty-four hours; or, what is still better, take ordinary plaster of Paris, wet it with the peroxide solution, and let it set "in a mould" so as to get a slab of it. This slab increases in activity for the first day or two after making, and retains its activity for a fortnight or more. Such a slab will give a good and dark picture in three or four seconds.

To show how similar the pictures produced by the peroxide and those by zinc are, pictures of a Japanese paper stencil, which had been paraffined to make it quite opaque, have been made by both processes, and are shown with other instances in which turpentine was used in the following slides. It is also very easy to obtain good pictures with the peroxide alone of the structure of paper, &c.; see, for instance, this one of a five-pound note and these of lace. Again, the strict similarity between the action of the peroxide and that of the metals and organic bodies is further shown by the fact that its action passes through the same media as theirs does; and here are good pictures formed by the action of the peroxide after passing through a sheet of these substances. How this singular transmission can be explained, I have treated of elsewhere, and time does not allow of my discussing the matter to-night.

There are many ways in which the bright, active zinc surface can be modified. Draw your finger across it, press your thumb upon it, and you stop its activity, as is shown by the picture it will give. Lay a printed paper on the zinc, and let the contact continue for three-quarters of an hour, at a temperature of 55°, then bring the zinc in contact with a sensitive plate, a picture of the printing is formed, but allow the contact between the zinc and printing to continue for eighteen hours at the same temperature, and the picture then given by the zinc is the reverse of the former one. Where the ink has been is now less active than the rest of the plate. Here are slides which show these positive and negative pictures. Another way of modifying the zinc surface

is interesting. You have seen that the ordinary zinc surface which has been exposed to air and moisture is quite inactive, but if a bright piece of zinc be immersed in water for about twelve hours, the surface is acted on; oxide of zinc is formed, showing generally a curious pattern. Now, if the plate be dried, it will be found that this oxide is strongly active, and gives a good picture of the markings on the zinc. The oxide evidently holds, feebly combined or entangled in it, a considerable quantity of the hydrogen peroxide, and it requires long drying or heating to a high temperature to get rid of it. Also, if a zinc plate be attacked by the hydrogen peroxide, the attacked parts become more active than the bright metal. Thus, place a stencil on a piece of bright zinc, and expose the plate to the action of an active plaster of Paris slab, or to active blotting-paper for a short time, then, on removing the stencil, the zinc plate will give a very good picture of the stencil. Any inactive body—for instance, a piece of Bristol board or any ordinary soft paper—can be made active by exposing it above a solution of peroxide, or, more slowly, by exposing it to a bright zinc surface. If, for instance, a copper stencil be laid on a piece of Bristol board, and a slab of active plaster of Paris be placed on the stencil for a short time, the Bristol board will even, after it has been removed from the stencil for some time, give a good picture of the stencil. Drying oil and other organic bodies may be used in the same way to change the paper. A curious case of this occurred in printing a coloured advertisement cut out of a magazine, for there appeared printing in the picture which was not in the original. This printing was ultimately traced to an advertisement on the opposite page, which had been in contact with the one which was used; thus this ghostly effect was produced.

I believe, then, that it is this active body, hydrogen peroxide, which enables us to produce pictures on a photographic plate in the dark. There are many other curious and interesting effects which it can produce, and which I should like to have shown you, had time permitted.

I would only add that this investigation has been carried on in the Davy-Faraday laboratory of this institution.

WILLIAM J. RUSSELL.

## THE ROYAL SOCIETY'S CONVERSAZIONE.

THE second of the two annual conversazioni of the Royal Society was held on Wednesday, June 21, and was attended by a large and brilliant company. Many of the objects of scientific interest exhibited in the various rooms of the Society were the same as were shown at the first (or gentlemen's) conversazione held on May 3, the most important of which were described in NATURE of May 11 (p. 44). In addition to the objects already referred to, the following were among the exhibits.

Mr. C. V. Boys, F.R.S., exhibited for Mr. R. W. Wood, of the University of Wisconsin:—(1) Silvered photographic grating. The grating of 2,000 lines to the inch is a contact print on albumen. It is then silvered and polished while wet. The brilliancy of the spectrum is very great. (2) Diffraction colour photograph (see p. 199). Mr. J. E. Petavel exhibited the molten platinum standard of light.

Mr. W. A. Shenstone, F.R.S., and Mr. W. T. Evans showed experiments on the making of tubes from rock crystal in the oxyhydrogen blowpipe flame.

The Parsons Marine Steam Turbine Co., Ltd., had on view: (1) model of the *Turbinia*, the first vessel propelled by steam turbine engines; (2) model of torpedo boat destroyer of 35 knots guaranteed speed and 10,000 I.H.P.; (3) model of Atlantic liner of 38,000 I.H.P. and 27 knots speed.

Mr. A. A. Campbell Swinton showed experiments with electrolytic contact breakers. Mr. J. W. Swan, F.R.S., exhibited experiments showing effects produced by the action of modifications of the Wehnelt-Caldwell interrupter. Mr. W. R. Pidgeon showed a new influence machine. Mr. Mackenzie Davidson exhibited an apparatus to enable Röntgen ray shadows upon a fluorescent screen to be seen in stereoscopic relief.

Prof. Ray Lankester, F.R.S., exhibited (1) collections of mosquitoes recently received at the Natural History Museum for study in reference to the connection of malaria with mosquitoes; (2) drawings of mosquitoes, by Mr. Ernest E. Austen.

Dr. Patrick Manson showed microscopic specimens showing the development of the parasite of malaria.

Dr. Allan Macfadyen, for the Jenner Institute of Preventive Medicine, exhibited cultures and microscopical specimens of certain pathogenic bacteria.

Dr. Gladstone, F.R.S., showed ancient metals from Egypt, Babylon, and Britain.

The Victoria and Albert Museum for the Seismological Committee of the British Association exhibited a Milne horizontal-pendulum seismograph, with specimen of the seismograms yielded by it.

Prof. Haddon, F.R.S., showed a small collection of polished stone implements from the Baram District, Sarawak, Borneo.

Prof. T. G. Bonney, F.R.S., exhibited diamonds in eclogite. Boulders of eclogite, &c., occur in the "Blue Ground" at the Newlands Diamond Mines, West Griqua Land. Two of these contain diamonds. Thus the diamond cannot have its genesis in the "Blue Ground," nor can the latter, containing true boulders, be an igneous rock.

Mr. Walter Gardiner, F.R.S., and Mr. A. W. Hill showed histological preparations of plant tissues demonstrating the "connecting threads" which traverse the cell walls and establish a means of communication between the several cells.

Dr. F. W. Oliver exhibited a collection of Cingalese Podostemaceæ. The specimens included the majority of the Cingalese representatives of this remarkable family of flowering plants.

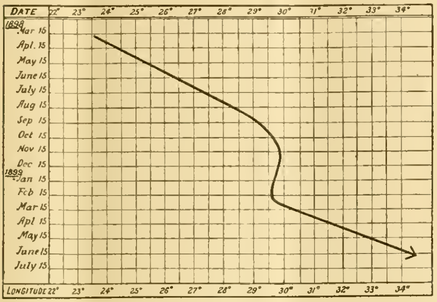
## THE RED SPOT ON JUPITER.

I HAVE frequently observed this object during the present apparition of the planet, but always found it exceedingly faint and only visible under good definition. Its aspect is that of a faint dusky stain attached to the northern side of the south temperate belt, and partially filling up the hollow formed in the great southern equatorial belt. With my 10-inch reflector—power 312—the following estimated times of transit were obtained, and I have added the corresponding longitude of the object:—

| Date. | Transit time. h. m. | Long. ° |
|---|---|---|
| 1898 November 29 | 19 55 | 31·9 |
| 1899 February 2 | 18 39 | 29·5 |
| 7 | 17 46 | 29·0 |
| 24 | 16 49 | 30·0 |
| 26 | 18 27 | 29·9 |
| April 19 | 11 20 | 32·0 |
| 26 | 12 3 | 30·8 |
| May 6 | 10 19 | 31·7 |
| 8 | 11 58 | 32·3 |
| June 4 | 9 18 | 34·4 |
| 6 | 10 57 | 34·8 |
| 9 | 8 26 | 34·4 |
| 11 | 10 4 | 34·0 |
| 14 | 7 32 | 32·9 |
| 16 | 9 13 | 34·4 |
| 21 | 8 20 | 33·5 |
| 23 | 9 58 | 33·1 |
| 26 | 7 29 | 33·7 |

This feature has shown a remarkable variation of motion during the last twelve months. In the winter there was a very decided acceleration of speed, but during the past three months the motion has been again retarded. The acceleration was first noticed here on the morning of February 3, when the marking came to the central meridian seven or eight minutes before its computed time. In the first half of 1898, and again during the last few months, the rotation period of the spot was nearly 9h. 55m. 42s., but for several months in the past winter the rate corresponded very nearly with 9h. 55m. 40·6s., the period employed by Mr. Crommelin in System II. of his ephemerides (*Monthly Notices*, November 1898). But, unfortunately, the precise character of the recent irregularity of motion cannot be determined, Jupiter having been too near the sun for effective observation during several months (August to November 1898).

The following diagram will, however, represent approximately the variation, which amounted to nearly one and a half seconds in the rotation period :—



My observation of 1898 November 29 was probably not very accurate, as the planet was low and very faint in the fog which prevailed. It is, however, in part confirmed by an observation obtained by Prof. G. W. Hough in 1898 December 10, who found the spot in the computed position, and saw no indication of the accelerated rate, which soon afterwards began to operate. In preparing the diagram I have, however, preferred to think that my autumn observation was a little late, as this requires a less sudden and extreme variation in the motion of the spot. This object should be carefully watched until the close of the present opposition, and the times of its transit secured on all possible occasions. There will be little difficulty in continuing observations until the end of August. If the red spot itself is not sufficiently distinct to be well observed when presented on the central meridian, transits of the middle of the hollow or bay in the southern side of the south equatorial belt will answer the purpose equally well.

Since the spot became a very prominent feature in 1878 it has exhibited an increasing rate of rotation, the period rising from 9h. 55m. 37s. to 9h. 55m. 42s. This increase has not been perfectly regular, for the motion has shown many irregularities similar to that which affected it during the past winter. No doubt the time will come when the maximum rate will be reached, to be followed thereafter by a marked shortening of the period. This appears to have been the case in 1859, and there is indication that the cycle of variations extends over a period of about 48½ years ; if so, we cannot expect a decided acceleration in the mean rate of the spot until the year 1907 or 1908.

There is every prospect that in a few years we shall be much better acquainted with the surface phenomena of Jupiter, and the variations affecting them, than we are at the present time. A very large number of useful observations were obtained in 1898, and many more are being secured during the present year. Observers are now generally recognising the necessity of accumulating observations of all the visible details of the surface, and determining the velocities of the various and varying currents in which they are situated.

The planet has recently afforded a singularly abundant display of spots and irregularities. Dark and white masses of material are thickly arranged near the equator, and from a partial investigation these appear to be moving rather slower than in 1898, the rate being now 9h. 50m. 25s., as against 9h. 50m. 23½s. during the previous opposition. A considerable number of white and dark spots are also distributed along the northern edge of the northern equatorial belt, which give a period slightly less than that of the red spot, but some of these markings are moving much more rapidly than others. The quickest of all is a small dark spot now in long. 145°, which has given a period of 9h. 55m. 15s., or about 27 seconds less than that of the red spot. In other latitudes a vast amount of detail is exhibited, and it is fortunate that the planet is being so sedulously studied by Mr. A. S. Williams, Prof. Hough, Mr. Gledhill, the Rev. T. E. R. Phillips, Captain Molesworth, and other able observers.

W. F. DENNING.

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The Harkness Studentship in Geology has been awarded to Mr. A. L. Hall, Caius, first class in Natural Science Tripos, Part II., 1899.

The following College awards in Natural Science are announced :—

Clare : Scholarships to Cassidy, Goodchild, and F. G. Smith ; Exhibition to H. B. Jackson.

Trinity Hall : Scholarship to H. S. Newbould.

King's : Scholarship to Barger ; Exhibitions to Kewley, Mollison, Matthews, and Cartwright.

Emmanuel : Exhibitions to Walker, Heaton, Nixon, Sutton, Austin.

Mr. G. T. Bennett (Senior Wrangler 1890) has been elected a Senior Fellow, and Mr. H. S. Carslaw (Fourth Wrangler 1894) a Junior Fellow, at Emmanuel College.

At the beginning of the Michaelmas term, the General Board will proceed to elect a University Lecturer in Physical Anthropology for five years, with a stipend of 50*l.* a year. Names must be sent in to the Vice-Chancellor by September 30.

At Caius College, E. P. Widdicombe (Downing) and H. E. Wimperis have been elected to Salomons Engineering Scholarships, and R. H. Yapp (St. John's) to a Frank Smart Studentship for Botany.

At Christ's College, Scholarships for Natural Science have been awarded or continued to Hocking, Howlett, Brown, Gottschalk, Leake, Hoffmann, Fox, Muff, and Cumberlidge.

At Sidney Sussex College, Science Scholarships have been awarded to Bullough, Coales, Colt, Fearnsides, Fyson, and Stenhouse.

---

SIR W. T. THISELTON-DYER, K.C.M.G., F.R.S., has been elected to an honorary studentship at Christ Church, Oxford.

DR. MAGNUS MACLEAN has been elected Professor of Electrical Engineering in the Glasgow and West of Scotland Technical College.

PROF. FRED W. MCNAIR has been elected president of the Michigan College of Mines. Prof. McNair has been for some years in charge of the department of mathematics and physics.

PROF. A. R. FORSYTH, F.R.S., Sadlerian professor of pure mathematics in the University of Cambridge, has had the honorary degree of LL.D. conferred upon him by the University of Dublin.

THE London School of Economics and Political Science, 10 Adelphi Terrace, W.C., offers the following research studentships, which will be awarded on examination in July : (1) One of 100*l.* a year, for two years, presented by the Hon. Bertrand Russell, Fellow of Trinity College, Cambridge. (2) One of 50*l.* a year, for two years. (3) The "Lucy Rose" studentship of 50*l.* a year, for two years, presented by Mr. Edward Rose—open to women students only. Preference will be given to a woman student sprung from the working classes. The studentships are intended to enable students to become trained investigators, and to promote the execution of definite pieces of original work relating either to past or present economic or political conditions.

THE *Times* states that the Association of Directors and Organising Secretaries for Technical and Secondary Education have addressed a memorial to the Government with regard to the alteration made in the Board of Education Bill in the Standing Committee of the House of Lords at the instance of Lord Spencer. The association entreat the Government to induce the House of Commons to restore Clause 3 (1) to its original shape, on the ground that the term "school supplying secondary education" (used in that clause) is a very wide one, and, if interpreted in the light of the report of the Royal Commission on Secondary Education, must include polytechnics, higher grade schools, science schools, art schools, commercial schools, and agricultural schools. These, it is submitted, are the very types of schools which are being founded or developed all over the kingdom by the county councils, which supply the pressing industrial needs of the day, and demand that guidance and encouragement which it is the object of the Bill to supply.

THE second reading of the Board of Education Bill was agreed to by the House of Commons on Monday. Sir John Gorst, in moving the second reading, explained that the object of the Bill is to enable the Government to create a department

of State which may have conferred upon it powers in relation to secondary education. The Royal Commission on Secondary Education recommended that there should be a central authority, a Government Department, in London, to supervise secondary education and local authorities in the country. The opinion of the Government is that the central authority in London must be created and arranged before the local authorities in the country can be usefully set on foot, and it is to organise and arrange a central department in London to exercise the sort of functions recommended by the Royal Commission that this Bill has been brought before Parliament. The Bill proposes the abolition of the existing Committee of Council on Education and to replace it by a Board of Education consisting of the First Lord of the Treasury, the Chancellor of the Exchequer, and the Secretaries of State for various departments, having a President and a Parliamentary Secretary in the same manner as the Local Government Board and the Board of Trade. To this new Board of Education are to be transferred all the powers and functions which are at present exercised by the Committee of Council, so that it will stand in relation to educational matters and the distribution of the science and art grants and technical instruction exactly in the same position, and have exactly the same powers, as the present Education Department possesses.

## *SCIENTIFIC SERIALS.*

*American Journal of Science*, June.—Othniel Charles Marsh—portrait and obituary notice.—The Camden Chert of Tennessee and its Lower Oriskany Fauna, by J. M. Safford and C. Schuchert. The latter describes in detail a peculiar chert formation discovered by the former.—Recent discovery of rocks of the age of the Trenton formation at Akpabok Island, Ungava, by J. F. Whiteaves. Describes the fossils collected by Dr. R. Bell, of the Canadian Geological Survey, on Akpabok Island, between Ashe Inlet and Fort Chimo, and concludes that they belong to a lower geological horizon than the Hudson River formation as at first supposed.—Studies in the Cyperaceæ, No 10, by T. Holm. Describes the North American species of *Fimbristylis*, Vahl.—On Roscœlite, by W. F. Hillebrand and H W. Turner. Roscœlite is a vanadium mica, some specimens of which show a tendency to crystallise in little rosettes. It occurs most frequently embedded in quartz at Placerville, California. It contains 45 per cent. $SiO_2$, 24 per cent. $V_2O_3$, 11 per cent. alumina, 10 per cent. potash, 4 per cent. water, and traces of magnesia and ferrous oxide.—Gravitation in gaseous nebulæ, by F. E. Nipher. If R be the radius of a spherical mass of gas of cosmical dimensions, and T its temperature, the product TR is constant. The heat capacity of such a gravitating mass is negative. If heat leaves the gas, it contracts and becomes warmer. The physical condition to be satisfied in order that a central mass or core, having a radius equal to that of the sun, should contain a mass equal to that of the sun, is that its temperature is 20 million degrees Centigrade. The pressure at the surface of this sphere is 366 million atmospheres. The average density of the spherical mass, which is three times the density at the surface of the hydrogen sun, is about 7 per cent. less than the average density of the sun itself, but the nature of the gas is immaterial. In the sun as it is, the rarefied external parts of the solar nebula have parted with their heat, and the temperature throughout the mass has ceased to be uniform. But the abolition of cosmical pressure has almost wholly compensated the fall in temperature of the sun from 20 millions at least to perhaps 10,000 degrees.

*Symons's Monthly Meteorological Magazine*, June.—Unprecedented frost in the United States in February 1899. In that month 64°·8 were recorded at Camden Town, being 2°·3 higher than any reading recorded in February in London during 104 previous years, while about the same time at New Orleans an equally unprecedented low reading of 7° (25° below freezing) was registered. Prof. Garriott, in charge of the forecast division, states that the most remarkable series of cold waves in the history of the Weather Bureau traversed the United States from the North Pacific to the South Atlantic coasts during the first half of February, damaging crops and fruit in the southern States to the extent of millions of dollars. The cause of this intense cold is ascribed to barometric depressions in the south, combined with a large area of high barometer over British north-west territory.—On a recent recurrence in weather: a lunar or 30-day period, by H. H. Clayton. The author has treated the temperatures observed at the Blue Hill Meteorological Observatory, from July 1898 to February 1899, in the same way as Mr. A. MacDowall has treated the temperatures for the same time observed at Greenwich. The figures show a well-marked period of about thirty days, but the interval is too short to determine whether the period had the exact length of the lunar period, or had any relation of cause and effect.

*Wiedemann's Annalen der Physik und Chemie*, No. 5.—A double trough refractometer, by W. Hallwachs. The author describes certain improvements in his differential interference refractometer for liquids, and measurements made with it on solutions of cadmium bromide, sugar, chloracetic acid, and chloracetates.—Optical properties of burnt-in gold and platinum films, by G. Breithaupt. Thin layers of gold, platinum, and other metals were burnt into glass or obsidian, and tested with regard to their dispersion. Gold showed normal dispersion, so did brass, when well polished with cotton wool. Platinum, steel, and nickel steel showed anomalous dispersion.—A new method of detecting electric waves, by A. Neugschwender. This is the author's second communication on the subject of his damp anti-coherer. He found that the establishment of conductivity between the two sides of a metallic slit on moistening it depended upon the presence of some metallic salt in the moisture which could be separated electrolytically. Under the microscope the metal so separated out forms a tree-like formation, which suddenly breaks up on the impact of electric waves, thus destroying the conductivity.—Determination of the pitches of Appunn's pipes by optical and by acoustic means, by F. A. Schulze. The author has repeated Appunn's determinations of the pitches of high pipes by the method of revolving mirrors, by Kundt's dust figures, and by Quincke's interference tube. He confirms Stumpf's result that the highest Appunn pipes have pitches assigned to them which are wrong by several octaves.—Determination of high pitches by difference tones, by C. Stumpf. The author defends the trustworthiness of the method of difference tones against Appunn's criticism.—On the refracted wave at so-called total reflection, by W. Voigt. Against Ketteler's criticism the author maintains that there exists a stream of energy parallel to the surface of the second medium in "total" reflection, and that this stream of energy is nothing else than a ray of light.—Thermal insulators, by W. Hempel. This is a comparison of the insulating properties of Dewar tubes silvered on the outer surface of the inner tube, with those of wool and feathers. Eiderdown turns out to be the most effective of the old insulators, as it is capable of maintaining a charge of solid carbonic acid and ether below −66° for an hour and a half, whereas the same charge surrounded by cotton or silk reaches −56° in the same time, and −33° when surrounded by an imperfect vacuum. At the same time, the charge remains below −70° in a Dewar tube, the initial temperature in every case being −79°.

## *SOCIETIES AND ACADEMIES.*

### LONDON.

**Royal Society**, May 18.—"Diffusion of Ions into Gases." By John S Townsend, M.A. (Dublin), Clerk Maxwell Student, Cavendish Laboratory, Cambridge. Communicated by Prof. J. J. Thomson, F.R.S.

In the paper upon this subject the principles of the theory of interdiffusion of gases are applied to the diffusion of ions produced in a gas by the action of Röntgen rays. When a gas is ionised in this way, and then removed from the action of the rays, the conductivity gradually disappears. If there are no electric forces acting on the gas, the loss of conductivity is due partly to the encounters between positive and negative ions, and partly the effect of the surface of the vessel which discharges those ions that come into contact with it.

The ions may be considered as a separate gas (A) mixed with the ordinary uncharged molecules (B), which are unaffected by the rays. When the mixture is passed along a metal tube there is a loss of conductivity, due to the ions coming into contact with the surface. A formula is given for calculating the rate of diffusion of the ions A into the gas B from this loss of conductivity, which was found experimentally. The following values were obtained for the coefficients of diffusion of ions into air, oxygen, carbonic acid, and hydrogen.

It was found that the rates of diffusion of the positive and negative ions differed more when the gas was dry than when it was moist.

*Values of $\kappa$ in Square Centimetres per Second.*

| Gas | $\kappa$ for + ions in dry gas | $\kappa$ for − ions in dry gas | $\kappa$ for + ions in moist gas | $\kappa$ for − ions in moist gas |

From the equation of motion

$$\frac{1}{\kappa} pu = -\frac{dp}{dx} + nXe$$

(where $p$ is the partial pressure of the ions, $n$ the number of ions per c.c., $e$ the charge on each ion, X the electric force at any point, and $u$ the velocity of the ion in the $x$ direction), it can be seen that when $\frac{dp}{dx} = 0$ the velocity $u$, due to the electric force X, is $\frac{nXe\kappa}{p}$.

If the potential gradient is one volt per centimetre, $X = \frac{1}{300}$ in electrostatic units, and the corresponding value of $u$ is $u_1 = \frac{\kappa e}{300} \cdot \frac{n}{p}$.

Let N be the number of molecules per c.c. in a gas at pressure P, equal to the atmospheric pressure and temperature 15° C., the temperature at which $u_1$ and $\kappa$ were determined.

The quotient $\frac{N}{P}$ may be substituted for $\frac{n}{p}$ in the above equation, and N$e$ is therefore obtained in terms of qualities which can be determined experimentally.

$$Ne = \frac{3 \; 10^8 u_1}{\kappa}, \text{ since } P = 10^6 \text{ in C.G.S. units.}$$

Substituting for $u_1$ the mean velocities given by Prof. Rutherford (E. Rutherford, *Phil. Mag.*, November 1897), and for $\kappa$ the mean coefficient of diffusion obtained for the dry gases, and the following values of N$e$ are obtained :—

| | |
|---|---|
| Air ... ... ... ... | $Ne_A = 1{\cdot}35 \; 10^{10}$ |
| Oxygen ... ... ... ... | $Ne_O = 1{\cdot}25 \; 10^{10}$ |
| Carbonic acid ... ... ... | $Ne_e = 1{\cdot}30 \; 10^{10}$ |
| Hydrogen ... ... ... | $Ne_H = 1{\cdot}00 \; 10^{10}$ |

Experiments on electrolysis show that one electrodynamic unit of electricity in passing through an electrolyte gives off 1·23 c.c. of hydrogen at temperature 15° C. and pressure $10^6$ C.G.S. units. The number of atoms in this volume is 2·46 N, so that if E is the charge on an atom of hydrogen in the liquid electrolyte

$$2{\cdot}46 \; NE = 1 \text{ electrodynamic unit of quantity}$$
$$= 3 \; 10^{10} \text{ electrostatic units.}$$

Hence $NE = 1{\cdot}22 \; 10^{10}$, the charge E being expressed in electrostatic units. Since N is constant, these numbers show that the charges on the ions produced by Röntgen rays in air, oxygen, carbonic acid, and hydrogen are all the same, and equal to the charge on an atom of hydrogen in a liquid electrolyte.

Prof. J. J. Thomson (J. J. Thomson, *Phil. Mag.*, December 1898) has shown that the charge on the ions in oxygen and hydrogen, which have been made conductors by Röntgen rays, is $6 \; 10^{-10}$ electrostatic units, and is the same for both gases.

Taking this value for the charge $e$, the number of molecules in a cubic centimetre of a gas is obtained :

$$N = 2 \; 10^{19}.$$

The weight of a molecule of hydrogen $\frac{\rho}{N}$ is therefore

$$4{\cdot}5 \; 10^{-24} \text{ grammes.}$$

In order to prove that the positive and negative ions have the same charge, the ratio of the coefficients of diffusion must be shown to be equal to the ratio of the velocities. This subject has been investigated by Prof. Zeleny (J. Zeleny, *Phil. Mag.*, 1898), and it was found that the negative ion travels faster than the positive ion in air, oxygen and hydrogen, the ratio of the velocities being 1·24 for air and oxygen, 1·15 for hydrogen, and 1·0 for carbonic acid.

Royal Society, June 15.—"On the Orientation of Greek Temples, being the Results of some Observations taken in Greece and Sicily in the month of May 1898." By F. C. Penrose, M.A., F.R.S.

The orientation of the Cabeirion Temple, near Thebes, on which the angle has been disputed (see p. 46 in my paper of 1897), was remeasured with the theodolite in May 1898, and the previous observations confirmed. An additional example is added from an archaic Temple of Neptune in the Isle of Poros, introducing the employment of the bright zodiacal star Regulus, which I had not before met with.

In Sicily the re-examination of the temples at Girgenti, where, in my former visit, I had relied for azimuth on the sun's shadow and the time, has enabled me to give to the elements some amendments in detail, the only point of consequence being that the orientation date of the temple named Juno Lacinia is brought within the period of the Hellenic colonisation of that city.

The most interesting point in the paper seems to be, that in the case of two Athenian temples, namely, the Theseum and the later Erechtheum—*i.e.* the temple now partially standing—it is shown that the days of those months on which the sunrise, heralded by the star, illuminated the sanctuary coincided exactly, on certain years of the Metonic cycle, with the days of the Athenian lunar months on which three important festivals known to be connected with at least one of those temples were held. The years so determined agree remarkably well with the probable dates of the dedication of those temples; and in the case of the first mentioned, the festival, which was named The Thesea, seems to leave little doubt that the traditional name of the temple, which has recently been much disputed, is the correct one.

"Collimator Magnets and the Determination of the Earth's Horizontal Magnetic Force." By C. Chree, Sc.D., LL.D., F.R.S., Superintendent of the Kew Observatory. Communicated by the Kew Observatory Committee of the Royal Society.

During the last forty years, there have been examined at Kew Observatory upwards of 100 collimator magnets used in observing the horizontal force and declination.

The "constants" of these magnets—temperature and induction coefficients, and moment of inertia—have been determined at the Observatory, and the tables based on these determinations have served to reduce magnetic observations at a large number of the leading magnetic observatories.

The present paper deals with the data recorded in the Observatory books for the constants specified above, and with other quantities—such as the "permanent" magnetic moment—which are deducible from the records. It determines the mean values of the several quantities for the instruments of the leading English makers, and investigates whether relations do or do not exist between them. It then deduces from the records the probable errors in the values of the several quantities, proceeding on the hypothesis that the methods of determining them are correct. It next examines, from a mathematical standpoint, the accuracy of the formulæ employed in reducing horizontal force observations, and, from a physical standpoint, the possibility of differences between the quantities determined at the Observatory and the quantities actually concerned in horizontal force observations.

The various sources of uncertainty are dealt with, and an attempt is made to ascertain to what extent they may affect the values found for the horizontal force.

The results of the paper are of too technical a character to admit of their being summarised briefly in an intelligible way.

Physical Society, June 23.—Mr. T. H. Blakesley, Vice-President, in the chair.—A paper on the magnetic hysteresis of cobalt, by Prof. Fleming, Mr. A. W. Ashton, and Mr. H. G. Tomlinson, was read by Mr. Ashton. A rectangular sectioned circular ring of cobalt was insulated with silk tape and wound over with four secondary coils put on at quadrantal positions. Over these secondary coils six primary coils were placed, and the ring was submitted to a complete set of magnetic tests with a ballistic galvanometer. From these observations various

curves have been plotted, and the results have been compared with a similar set of readings taken on a cast iron ring. A chemical analysis of the cobalt showed that it contained about 1 per cent. of iron and 1 per cent. of nickel. The authors conclude that, although in general form the magnetisation curve for cobalt resembles that of cast iron, its hysteresis exponent is similar to that of annealed soft iron. The absolute hysteresis values corresponding to various maximum flux densities are, however, not very different from those of a typical variety of cast iron. Prof. Everett referred to the fact that the sample of cobalt contained about 1 per cent. of iron, and said that it would be interesting to know how cobalt free from iron would behave. The Chairman said that the hysteresis curves obtained from the step by step method could not be applied to dynamos, because the time taken to perform the cycle altered the shape of the curve. He would like to see the curves for cobalt determined in cases where the cycles were quickly executed.—A discussion on physical tables was commenced by Mr. J. Lupton. Mr. Lupton briefly reviewed some of the difficulties met with in compiling physical tables and in keeping them up to date. He divided them into four classes according to their objects, and criticised several well-known books of constants. He pointed out the danger of leaving out apparently obvious figures, and referred to the necessity for accurate proof reading. Prof. Everett said that in his work he had aimed at giving an idea of the meanings of various numbers, rather than stating them with great accuracy. He drew attention to the difficulty of condensing large series of numbers into a clear and concise table. Mr. Watson said that it was important that the units in which numbers were expressed should be stated at the head of each table. The Chairman having pointed out one or two small points to be attended to in the compilation of tables, the Society adjourned until next October.

**Chemical Society**, June 15.—Prof. T. E. Thorpe, President, in the chair.—The following papers were read:—On the decomposition of chlorates, with special reference to the evolution of chlorine and oxygen, by W. H. Sodeau. The author concludes that on heating barium chlorate, two reactions proceed simultaneously; (*a*) an exothermic decomposition into chloride and oxygen, and (*b*) an endothermic decomposition into oxide, chlorine and oxygen.—Action of hydrogen peroxide on formaldehyde, by A. Harden. Hydrogen peroxide and formaldehyde react in presence of much soda in accordance with the following equation:

$$H_2O_2 + 2CH_2O + 2NaHO = 2HCO_2Na + H_2 + 2H_2O.$$

With excess of formaldehyde reaction proceeds rapidly, whilst in presence of excess of hydrogen peroxide it proceeds slowly and incompletely. The behaviour of other oxides towards formaldehyde and soda has also been investigated.—Homocamphoronic and camphononic acids, by A. Lapworth and E. M. Chapman. α-Dibromocamphor is rapidly oxidised by nitric acid in presence of silver nitrate, with formation of small quantities of a nitro-compound, $C_{10}H_{14}N_2O_6$, and a tribasic acid, $C_{10}H_{16}O_6$, named homocamphoronic acid; the latter yields on heating first an anhydro-acid, and then a ketonic acid, $C_9H_{14}O_3$, termed camphononic acid.—Action of silver compounds on α-dibromocamphor, by A. Lapworth.—The colouring matter of cotton flowers, by A. G. Perkin. The flowers of the cotton plant, *Gossypium herbaceum*, contain a glucoside, gossypetin, $C_{16}H_{12}O_8$; it is a colouring matter, yields a hexacetyl-derivative, and resembles thujetin.—Experiments on the synthesis of camphoric acid, by H. A. Auden, W. H. Perkin, jun, and J. L. Rose. Ethyl isoamylacetoacetate was converted into ethyl α-isoamyl-ββ-hydroxycyanobutyrate, which on hydrolysis yielded methylhydroxyisoamylsuccinimide; the latter on further hydrolysis yielded the corresponding acid

$$COOH.CMe(OH).CH(C_5H_{11})COOH,$$

from which it was hoped by elimination of water to synthesise camphoric acid. The attempt was not successful.—Methylisoamylsuccinic acid, i., by W. T. Lawrence.—Condensations of anhydracetonebenzil and its analogues with aldehydes, by F. R. Japp and A. Findlay.—Triphenyloxazolone, by F. R. Japp and A. Findlay.—Interaction of phenanthraquinone, acetophenone, and ammonia, by F. R. Japp and A. N. Meldrum.—Furfuran derivatives from benzoin and phenols, by F. R. Japp and A. N. Meldrum.—Interaction of benzoin with phenylenediamines, by F. R. Japp and A. N. Meldrum.—The condensation of ethyl salts of acids of the acetylene series with ketonic compounds, by S. Ruhemann and A. V. Cunnington.—Dextro-ac-tetrahydro-β-naphthylamine, by W. J. Pope. Inactive ac-tetrahydro-β-naphthylamine may be resolved into its optically active components by means of its dextro-α-bromocamphorsulphonate; the pure dextro-compound was thus prepared.—The resolution of racemic tetrahydroparatoluquinaldine into its optically active components, by W. J. Pope and E. M. Rich. Inactive tetrahydroparatoluquinaldine may be resolved into its optically active components by crystallisation with dextro-α-bromocamphorsulphonic acid. — Isomeric salts of hydrindamine containing pentavalent nitrogen, by F. S. Kipping. The author has endeavoured to resolve α-hydrindamine into its optically active components by Pope and Peachey's method with bromocamphorsulphonic acid and by crystallisation with cis-π-camphanic acid; two salts are formed in each case, but the regenerated base is optically inactive.—Synthesis of phenoketoheptamethylene, by F. S. Kipping and Miss L. Hall.—Organic compounds containing silicon, by F. S. Kipping and L. L. Lloyd. The authors have prepared triphenylsilicol, $(C_6H_5)_3$ Si.OH, its acetyl derivative, $(C_6H_5)_3$ Si.OAc, and the corresponding ether, $(C_6H_5)_3Si.O.Si(C_6H_5)_3$.—The velocity of reaction before complete equilibrium, by M. Wilderman.—The ultra-violet absorption spectra of albuminoids in relation to that of tyrosin, by A. W. Blyth.—An explanation of the laws which govern substitution in the case of benzenoid compounds (third notice), by H. E. Armstrong. The author advocates the view that in compounds which ordinarily furnish meta-di-derivatives, the radicle ($NO_2$, $CO_2H$, &c.) is not only unattractive and possessed of little or no ortho-para-orienting power, but even exercises an inhibiting influence on these positions.—The colouring matters of dyer's broom and heather, by A. G. Perkin and F. G. Newbury.

**Linnean Society**, June 15.—Dr. A. Günther, F.R.S., President, in the chair.—The President exhibited a living specimen of a tree-frog (*Polypedates quadrilineatus*) which was introduced accidentally into Kew Gardens with a consignment of plants from Singapore. This is not the first instance of accidental introduction of a tropical frog into the Royal Gardens, Kew. Some five years ago a species of *Hylodes*, from Dominica, appeared in some numbers in several of the propagating-houses, and has evidently reproduced its species since arrival.—Mr. W. Whitwell exhibited: (1) The only known British specimen of *Botrychium matricariaefolium*, A. Braun, gathered in July 1887 on the seashore at Stevenston, Ayrshire (*Journ. Bot.*, 1898, pp. 291–297). (2) An undescribed variety of *Asplenium Ruta-muraria*, Linn., from an old wall on Dartmoor, about five miles from Plympton. (3) A specimen of rye with two ears on the same stalk, gathered at Romsey, Hants.—Mr. Robert T. Günther read a paper on the natural history of Lake Urmi in N.W. Persia, the neighbourhood of which he had explored during the autumn of last year. The collections which he had made there had been worked out by a number of specialists, each of whom had furnished a report on the specimens submitted to him. In many of the groups (notably amongst the fishes) several new species were described; and a good deal of interest centred in the skull and horns of a wild sheep which had been picked up on Koyun Daghi, the largest island in Lake Urmi. Although no living wild sheep were observed there during the traveller's short visit, small herds were reported to exist, the island, with lofty and precipitous hills, being apparently well adapted to their requirements. The head in question, that of an adult ram, unlike the typical *Ovis orientalis* found in Northern Persia and Armenia, more nearly approached that of *Ovis ophion*, the mufflon of Cyprus, a curious and unexpected resemblance.—Dr. A. B. Rendle read a paper entitled "A systematic revision of the genus *Najas*," a primitive genus of Monocotyledons containing about thirty known species, generally distributed in both Old and New Worlds, and consisting of submerged herbs, often of great delicacy, growing in mud in fresh or brackish water.

**Royal Meteorological Society**, June 21.—Mr. F. C. Bayard, President, in the chair.—Dr. R. H. Scott, F.R.S., read a paper on the heavy falls of rain recorded at the seven observatories connected with the Meteorological Office during the twenty-eight years 1871–98. The data has been derived from the records of the Beckley self-recording rain gauges at the following places:—Valencia, Armagh, Glasgow, Aberdeen, Falmouth, Stonyhurst, and Kew. These records have been tabulated for each hour, and it is from these hourly tabulations

that Dr. Scott has extracted the heavy falls. He finds that Falmouth has the greatest frequency of heavy falls, the next station being Valencia, and then Stonyhurst. The most exceptional fall during the whole period was at Glasgow at five p.m. on August 11, 1895, when as much as 0·80 in. was collected in ten minutes. The information given in this paper is likely to be of much service to engineers who want to know the rate at which rain sometimes falls in short periods.—A paper by Mr. J. Baxendell, describing his new self-recording anemoscope, was read by the Secretary. This instrument, which records the direction of the wind on an open scale, has been in use at Southport for more than a year, and works very satisfactorily. The vane, which is an exceedingly light, but large double-bladed, one, is sensitive even in light airs, and is steady in the strongest gales. The records from this anemoscope, which were exhibited at the meeting, were very clear and of an interesting character, and showed the instrument to be a valuable companion to the Dines pressure tube anemometer.—A paper, by Mr. R. C. Mossman, on the average height of the barometer in London, was also read by the Secretary. Some years ago Mr. H. S. Eaton worked out the mean monthly and annual height of the barometer in London for one hundred years. Mr. Mossman has carried on this discussion for a further period of twenty years; but he finds that the results for the one hundred and twenty years are practically identical with those for one hundred years.

**Zoological Society**, June 20.—Dr. Albert Günther, F.R.S., Vice-President, in the chair.—Mr. W. E. de Winton made some remarks on a small collection of mammal-skins from British Central Africa, which had been transmitted to Mr. Sclater by Mr. Alfred Sharpe, C.B. Mr. de Winton also exhibited the mounted heads of a male and female red-flanked Duiker (*Cephalophus rufilatus*, Gray), collected by Mr. J. F. Abadie in the Borgu country of the Niger district; and the skull of a male of the same species obtained by Captain W. Giffard near Gambaga, in the back country of the Gold Coast.—The Hon. Walter Rothschild read a memoir on the cassowaries, which contained notes on and an enumeration of the species and geographical races of these birds.—Mr. C. W. Andrews gave a description of a new type of bird, the skull and pelvis of which had lately been discovered by Mr. W. H. Shrubsole, enclosed in a nodule in the London clay of Sheppey.—A communication from Mr. J. Y. Johnson treated of the antipatharian corals of Madeira, and of a specimen from the West Indies in the British Museum.—A communication was read from Mr. Stanley S. Flower, containing notes on the Proboscis monkey (*Nasalis larvatus*) made on a young male example of this animal which had lived for a short time in the Egyptian Zoological Gardens at Ghizeh, Cairo.—A communication from Mr. Alexander Sutherland on the temperature of the Ratite birds was based on observations made on specimens of birds of this family in the Society's Gardens.—Mr. G. A. Boulenger, F.R.S., read a paper on the American Spade-foot (*Scaphiopus solitarius*, Holbrook), in which he pointed out that this frog had affinities with both *Pelobates* and *Pelodytes*, and that these three genera together formed one natural family, viz. the *Pelobatidae*.—Mr. W. L. H. Duckworth read a paper containing an account of the female chimpanzee, known as "Johanna," living in the menagerie of Messrs. Barnum and Bailey. The history and habits, diet in captivity, intellectual attainments, physical proportions, and appearance of this ape were dealt with in the paper, as also was the question of species, the author regarding the specimen as allied to the chimpanzees rather than to the gorilla.—A communication from Mr. R. Lydekker gave an account of a new species of Kob antelope (specimens of which had recently been received in a collection from Sierra Leone), under the name of *Cobus nigricans*. Mr. Lydekker also drew attention to skins of a Kob from Barotseland, recently received at the British Museum, which he had identified with *C. senganus*. The specimens of the latter form he stated differed so slightly from the type of *C. vardoni* that he was inclined to regard them as not worthy of specific rank, and to refer them to a subspecies which he proposed to call *C. vardoni senganus*.—Mr. Lydekker also sent a description of a specimen of a leopard from the Caucasus, belonging to the collection of Prince Demidoff, which differed in several respects from the common leopard, and which he proposed to regard as a subspecies under the name of *Felis pardus tulliana*.—A third communication from Mr. R. Lydekker related to the former existence of a Sirenian of some kind in St. Helena, which had been noticed by former observers in that island, but to which no reference had been made by recent authors.—Mr. F. E. Beddard, F.R.S., read a paper on the brain of the Capybara (*Hydrochoerus capybara*) based on examination of specimens in the Society's Gardens.—Mr. Beddard also read a paper, prepared by himself and Miss Sophie M. Fedarb, containing notes on the anatomy of the worms *Perichaeta biserialis* and its variations and *Trichochaeta hesperidum*.—Dr. Woods Hutchinson read a paper on the zoological distribution of tuberculosis from observations made mainly in the Society's Gardens. Of 215 autopsies made in the prosector's room during the past six months, 49 presented the lesions of tuberculosis, *i.e.* 25·3 per cent. of the mammals and birds. This mortality fell most heavily upon the ruminants and gallinæ, and least so upon the carnivores and raptors. Race or family appeared to exert little influence upon susceptibility, mode of housing only a small amount, and food and food-habits much more. A close correspondence appeared to exist between immunity and the relative size of the heart in both birds and mammals.—A communication was read from Dr. A. G. Butler containing an account of a small collection—consisting of nineteen specimens—of butterflies sent home from Muscat by Lieut.-Colonel A. S. G. Jayakar.—Dr. J. W. Gregory read a paper containing an account of the West Indian species of corals of the genus *Madrepora*.—A communication was read from Marquis Ivrea on the black roedeer of Hanover.

### EDINBURGH.

**Mathematical Society**, June 9.—Dr. Morgan, President, in the chair.—The following papers were read:—Systems of circles analogous to Tucker circles, part iii.; systems of conics connected with the triangle; systems of spheres connected with the tetrahedron, Mr. Third; "La perspective d'une conique est une conique" (démonstration élémentaire), M. L. Leau.

### PARIS.

**Academy of Sciences**, June 19.—M. van Tieghem in the chair.—On a class of isothermic surfaces connected with the deformation of surfaces of the second degree, by M. Gaston Darboux. A further development of the subject dealt with in a previous note.—On the determination of the integrals of the equations to partial derived functions of the second order by their values on a closed curve, by M. Émile Picard.—Late watering of the vine, by M. A. Müntz. Towards the end of a dry season the growth of the grapes is impeded and small yields are obtained, although the wine produced is often of higher quality. Nevertheless, this increased value does not compensate for the diminished quantity, and artificial watering is therefore resorted to. The author has experimented on the effects of this practice, and finds that the grapes thus treated increase in weight to the extent of 25 to 30 per cent. as compared with the untreated fruit. Part of this increase is due to simple absorption of water, but not the whole, since there is a notable increase in the sugar and vegetable acids. It is noteworthy that delayed watering causes a retrogression in the ripening process, the relative proportions of the sugar and acids becoming what they were at an earlier part of the year.—Note on the toxicity of the urine of children, more especially in cases of appendicitis, by MM. Lannelongue and Gaillard. The toxicity of the urine of normal children is inferior to that of the urine of adults, but is largely increased in cases of acute appendicitis. The colour of the pathological fluid is also more marked, and the density and amount of extractives present are greater.—Electromotive force produced in a flame by magnetic action, by M. R. Blondlot. If two platinum wires are placed symmetrically at the opposite edges of an ordinary gas flame and connected with a capillary electrometer, only a feeble oscillatory movement of the mercury is noticed, but a steady deflection is produced when the flame is placed between the poles of an electromagnet. This phenomenon is doubtless due to electromagnetic induction, the effect of the heated gases constantly ascending in the magnetic field being the production of an electromotive force the direction of which is normal both to the lines of force and to the direction in which the gases are moving.—Influence of the manner of introduction on the therapeutic effects of antidiphtheritic serum, by M. S. Arloing. From the experiments described it appears that with the dog the therapeutic effect of the serum is more marked when it is introduced into the blood instead of into the connective tissue, whereas with the guinea-pig the reverse is the case.—Observations made at the Bordeaux

Observatory on the partial eclipse of the sun, June 7, by MM. Féraud, Doublet, Esclangon and Courty.—On some anomalous surfaces applicable to a plane, by M. H. Lebesgue. The author shows that developable surfaces are not the only surfaces which are applicable to a plane.—On the calculation of the integrals of differential equations by the method of Cauchy-Lipchitz, by M. Paul Painlevé.—Comparison of the velocities of propagation of electromagnetic waves in air and along wires, by M. C. Gutton. The two velocities in question have been compared by a more exact method than those hitherto employed, and their equality verified to within 1 in 200.—Electrolytic action observed in the neighbourhood of a Crookes' tube, by MM. H. Bordier and Salvador. When an electrolytic cell consisting of two plates of copper or zinc immersed in a solution of copper or zinc sulphate is connected with a delicate galvanometer and placed in proximity to a Crookes' tube in action, a notable polarisation of the electrodes of the cell is observed. The effect is not due to the action of the X-rays, but is caused by a secondary, dark discharge from the anode and kathode of the tube, which is equivalent to a current of high electromotive force but of feeble intensity.—On magnet steels, by M. F. Osmond. Experiments on the magnetic properties of steels containing varying amounts of manganese and of nickel.—Researches on the vapours emitted by the two varieties of mercuric iodide, by M. D. Gernez. Experiments are described which show that the vapour of mercuric iodide, whatever its origin, is capable of condensing to form, at the same temperature, either the red or the yellow crystals of the compound, according as either variety is employed as a starting point for crystallisation. The condition of the vapour is, in fact, analogous to that of melted sulphur, from which three forms of crystals may be obtained at will according to the form of the crystal introduced as a nucleus.—Remarks on the oxides of sodium and on the chemical function of water as compared with that of hydrogen sulphide, by M. De Forcrand. The author discusses the heats of formation of the oxides of sodium, as determined by himself and by other observers, and endeavours to show that the two hydrogen atoms in the molecule of water are distinctly different in function, whereas in hydrogen sulphide they are of equal value. Water is therefore to be considered as an unsymmetrical, hydrogen sulphide as a symmetrical, compound, as may be indicated by the formulæ H—OH and H—S—H respectively.—On the decomposition of carbonic oxide in the presence of metallic oxides, by M. O. Boudouard. The experiments described in previous communications have been extended to a temperature of 800° C.; the metallic oxides employed were those of cobalt, nickel, and iron. The decomposition is a function of the time, the amount of carbonic anhydride formed increasing in a regular manner until the limit, at 800°, of 7 per cent. is reached. The velocity of the reaction is much greater at 800° than at 650°.—On the decomposition of carbonic anhydride in the presence of carbon, by M. O. Boudouard. An extension of previous researches on this reaction. The limiting composition of the gaseous mixture at 800° is 93 per cent. of carbonic oxide and 7 per cent. of carbonic anhydride. At 925° there still remained 4 per cent. of carbonic anhydride.—On a lower homologue of citric acid, by M. Augustin Durand. By treating the sodium derivative of ethylic oxaloacetate with hydrocyanic acid and hydrolysing the cyanhydrin thus produced, the authors have obtained a new acid of the composition

$$COOH.CH_2.C(OH).(COOH)_2.$$

Experiments are in progress for the preparation of other homologues of citric acid.—On Morren's glands in European *Lumbricoides*, by M. Édouard de Ribaucourt. On the fall of leaves and the cicatrisation of the wound, by M. A. Tison.—The upper layers of the Jurassic soil in Bas-Boulonnais, by M. Munier-Chalmas.—Crystallisation of blood-albumin, by Mlle. S. Gruzewska. Abundant crystalline deposits of albumin were obtained from the blood of the guinea-pig by employing a low temperature and working with solutions almost saturated with ammonium sulphate.

NEW SOUTH WALES.

**Royal Society**, May 3.—The President, G. H. Knibbs, in the chair.—The following gentlemen were elected officers for the current year:—President, W. M. Hamlet; Vice-Presidents, Prof. Anderson Stuart, Charles Moore, Prof. T. W. E. David, Henry Deane; Hon. Treasurer, H. G. A. Wright; Hon. Secretaries, J. H. Maiden, G. H. Knibbs.—The theme of the anniversary addres delivered by the President, Mr. G. H. Knibbs, was the influence of science upon civilisation.

AMSTERDAM.

**Royal Academy of Sciences**, May 27.—Prof. H. G. van de Sande Bakhuyzen in the chair.—Prof. Kamerlingh Onnes presented, for publication in the *Proceedings*, a paper by Dr. L. H. Siertsema, entitled "Measurements of the magnetic rotation of the plane of polarisation in oxygen at various pressures." The magnetic rotation in oxygen was measured in the same way as was formerly done in the case of pressures of 97, 73, 49 and 38 atmospheres, and at these pressures it was found to be proportional to the density of the gas.—Prof. van Bemmelen presented, on behalf of Dr. F. A. H. Schreinemakers, for publication in the *Proceedings*, a paper entitled "On the system water, phenol, acetone."—Prof. Lobry de Bruyn communicated the results of the inquiries of Prof. Holleman, who has determined how, on the nitration of benzoic acid and its methyl and ethyl esters, the proportion of the quantities of the three isomeric mononitro-derivatives, which are formed at the same time, varies with the temperature (−30°, 0° and +30°).—Prof. van de Sande Bakhuyzen presented, on behalf of Mr. H. F. Zwiers, a paper on the system of Sirius according to the most recent observations.

## *MAMMALIAN DISTRIBUTION.*

*The Geography of Mammals.* By W. L. and P. L. Sclater. Pp. xviii + 335. Illustrated. (London: Kegan Paul, Trench, Trübner, and Co., Ltd., 1899.)

THIS work may be best described as being of an extremely conservative nature; so conservative indeed that the authors seem under the impression that scarcely any improvement or alteration in views advanced many years ago can by any possibility be rendered necessary through the general progress of science and the work achieved by other investigators. It may likewise be described as a unionist production, for, in addition to the names of the two authors which appear on the title-page, we are told in the preface that two other gentlemen have assisted in the compilation of the lists of genera. Unfortunately, although there has doubtless been "a union of hearts," a union of pens is conspicuous by its absence; so that, as will be shown in the course of this notice, there are many glaring incongruities between different portions of the work, while the want of correspondence in the nomenclature employed can scarcely be designated as anything less than appalling.

The work really consists of three distinct sections. First, we have seven chapters by Mr. W. L. Sclater on the terrestrial regions into which the globe may be mapped out from the distribution of its mammals. Secondly, there is a chapter by the senior of the two authors on the marine regions indicated by the distribution of cetaceans and sirenians. And, thirdly, the seven last chapters of the book, by the same hand, treat of the distribution of the various orders of mammals.

As the results of their investigations, both from the strictly geographical and the purely zoological standpoint, the authors are convinced that the regions originally proposed by the senior of the two, chiefly on the evidence of passerine birds, are also, in the main, those best adapted to show the present distribution of mammals. For reasons which will be apparent to many of his readers, the present reviewer has no intention on this occasion of recapitulating the arguments which have been used against some portions of this grouping. It will suffice to say that he does not agree with them; and criticism may well be left to American zoologists, who may be trusted to fight strongly in defence of their own views, which receive, if we may say so, somewhat scant justice at the hands of the Messrs. Sclater. Taking, then, the groupings of the regions as they stand, attention may be concentrated on some of the details of the book before us.

Perhaps the most satisfactory feature of the book is the prominence given to the three primary divisions—Arctogæa, Neogæa, and Notogæa—into which nearly all authorities are agreed that the land surface of the globe should be parcelled out from a distributional point of view. We should, however, have much preferred seeing these great divisions indicated in the general map forming the subject of Plate I.; and the component "regions" into which the first is subdivided marked by colour-shadings. As it is, the essential difference between the single regions respectively constituting the two latter divisions and those included in the first are totally unapparent. One very distinct improvement on all previous works on the subject we are happy to recognise. This is the separation of Celebes from the Australian and its transference to the Oriental region. But we think the authors have scarcely gone far enough, and that Timor and the Moluccas might likewise have shared in the same westerly shift. In any case, it seems scarcely justifiable to retain the term "Wallace's line" solely for the small channel separating Bali from Lombok, seeing that it is generally taken to include the one between Borneo and Celebes.

Admitting that the authors and the present reviewer "agree to differ" in regard to the number of regions, the work would have had a greater value had it been a thoroughly up-to-date and trustworthy *résumé* of what we take leave to call the old-fashioned view. But is this really the case? As is stated in the preface, the seven chapters by the junior author first made their appearance in the *Geographical Journal* between the years 1894 and 1897. They are now reprinted "with some slight alterations." Bearing in mind the rapid movements of science in all its branches, to which allusion is likewise made in the preface, is it, we ask, fair to the author himself and the public at large to make what may have been very good in its way in 1894 do duty in 1899?

To take one instance out of many, we find it stated on pp. 53 and 54 that "there can be *no doubt*[1] that the Galapagos have never, at any period of their history, been joined to the mainland." Now, so far back as 1892 (so that, by the way, the statement might have been included in the original paper) the late Dr. George Baur[2] wrote the following sentence:—"That it has been made probable that the Galapagos are of *continental* origin, I consider one of the most important results of the expedition." And this view Dr. Baur has subsequently endeavoured to develop in not less than five separate communications. Of course the authors have every right to take their own view, but they have no justification either to ignore the existence of an opposite opinion, or for the use of the words "no doubt."

Dogmatism is indeed much too apparent throughout the book. For example, on p. 217 we find the statement (by the senior author) that certain views

"would tend in favour of the now generally accepted doctrine that the principal masses of land and water are not of modern origin, but have existed in *their present shapes throughout all ages.*"

In regard to this astounding statement, we may well ask whether the author is acquainted with a work which has attained some celebrity on the continent—to wit, the second edition of Neumayr's "Erdgeschichte." If not, his attention may be directed to the map on p. 203 of the second volume; and if he can say that the continents then retained "their present shapes," he evidently puts a different interpretation on the word shape than the one to which we are accustomed.

But without the aid of foreign works the author may,

1 The italics in this and other quotations are the reviewer's.
2 Proc. Amer. Antiquarian Soc for 1891.

we think, in this connection be "hoisted with his own petard." On turning to pp. 236–7 we find the following statement :—

"This fact would seem to show that the ancient 'Lemuria,' as the hypothetical continent which was originally the home of the Lemurs has been termed, *must* have extended across the Indian Ocean and the Indian Peninsula to the further side of the Bay of Bengal and over the great islands of the Indian Archipelago."

Is this quite a case of the retention of their present shapes by the continents?

But there is more to be said in regard to this paragraph, and especially in respect to the use of the objectionable *must*. Turning back to pp. 149–50, we find the junior author discussing the theories that have been advanced as to a direct communication between Africa and India across the Indian Ocean. As the result of his own criticism we have the following very definite statement :—

"This land connection may be of use in explaining the distribution of some of the lower vertebrates, but is of *no assistance so far as the Mammals are concerned;* because in those early times it is probable that none of the families or even orders of our present Mammals had arisen."

And yet in the passage previously quoted we are calmly told by the senior author that the old home of the Lemurs *must* have extended across the Indian Ocean! Comment is superfluous!

Possibly if this were a single isolated instance it might be passed over as one of those unfortunate slips to which the most careful of us are occasionally liable. But it is by no means so; and, out of several others, we select another instance.

On p. 216 Dr. Sclater, in treating of seals, writes that

"In former ages there must have been some barrier in the Atlantic which did not exist in the Pacific to stop their progress northwards. The only barrier one can imagine that would have effected this must have been a land uniting South America and Africa across which they could not travel."

Apart from the question whether such a barrier accords with the dictum as to the retention of their shape by the continents at all periods of the earth's history, we find Mr. W. Sclater making the following very definite statement on p. 55 :—

"Everything points to the conclusion that during a long geological age, probably *throughout the greater part of the Tertiary period*, *South America* was entirely *isolated* from the rest of the world."

If, therefore, an Atlantic barrier stopped the northward progress of the seals, it must have existed, at the very latest, in the Lower Eocene period; and at present we are unaware of the existence of seals previous to the Miocene!

The truth is (and there are occasions when plain-speaking is necessary) neither of the authors, nor the two gentlemen who have assisted them, have the slightest practical acquaintance with palæontology, and (to use a word "made in Germany") *erdgeschichte*. And they would have been well advised had they left such subjects severely alone, and made what they could out of the present distribution of animals. That a true geographical scheme of distribution can be made on such knowledge alone we are not prepared to admit; but that is a detail.

As an example of palæontological ignorance, we may refer to the twice-repeated statement (pp. 189 and 195) that fossil camels are unknown in Europe; and yet one from Rumania has been described some time since. Again, on p. 80 we are told that opossums occur in the Santa Cruz beds of Patagonia; and here, as well as on p. 9, they are consequently regarded definitely as members of the endemic South American fauna. And yet on p. 156 it is stated that the Virginian opossum "may be a survivor rather than an intruder in North America." On p. 323 we meet with the statement that whether the same animal is certainly indigenous in North America, "or whether it may not have extended its range northwards from Central America in more recent times, it is hard to say." All this confusion arises from insufficient acquaintance with the facts; what we believe these to be need not be mentioned here.

Allusion has already been made to the want of reference to modern literature in the case of the Galapagos islands, and this is also noticeable in other cases. For instance, what can be thought of the omission of all reference to Dr. Merriam's papers on distribution in the introductory chapter? Here, too, mention should have been made of Mr. Pocock's distribution of Arachnida, seeing that it takes much account of other groups. Mr. Baldwin Spencer's important observations on the origin of Australian Mammals, published in the "Results of the Horn Expedition," are likewise unnoticed; as are those of Dr. Schärff on that of the European fauna. Somewhat curiously, too, a small work published a few years ago on mammalian distribution, which has been deemed worthy of translation into German, likewise receives no recognition.

In addition to all the foregoing (to say nothing of other) inconsistencies and omissions, the present work is, unfortunately, open to very severe criticism on account of carelessness in proof-reading, and the lack of correlating the names used in the later pages with those that precede them. Since the book appears to be written to a certain extent for amateur zoologists, these errors are the more to be deprecated. To quote all that we have detected would be impossible, and a few must accordingly suffice.

To the beginner it will be decidedly puzzling to reconcile the statement on p. 2, that mammals may be divided into eleven orders, with the one on p. 219 that the number of such divisions is fourteen; more especially as the monkeys are classed under the name Primates in the one place, and as Quadrumana in the other. Again, the uninitiated will be somewhat disconcerted to find the dormice figuring as *Myoxidae* on p. 182, and *Gliridae* on p. 276. Neither is it conducive to clearness to find the Picas described as *Lagomys* on p. 166, *Ochotoma* on p. 274, and *Ochotona* on p. 281. Minor discrepancies in the spelling of family and generic names, such as *Phyllostomatidae* on p. 265 against *Phyllostomidae* on p. 269, *Pteropidae* on p. 64 against *Pteropodidae* on p. 161, and *Haplodon* on p. 159 against *Haplodontia* on p. 272, are so numerous that the corre-

spondences are almost in a minority when compared with the discrepancies. More serious is *Hydropotes* on p. 139 against *Hydrelaphus* on p. 296. But the culmination is reached when we find, pp. 115–6, *Otocyon* twice identified with the Cape hunting-dog, and, p. 313, the giant *Armadillo* miscalled the giant *Kangaroo!*

With regard to the authors' view on nomenclature, which we venture to regard, with certain curious exceptions, as somewhat old-fashioned, it is not our intention to offer any general criticism on this occasion. We may, however, point out that in rejecting the earlier *Mazama* in favour of the later *Cariacus* for the name of the American deer, they are led into a difficulty when they come to sub-genera; *Dorcelaphus* (a sub-genus) antedating *Cariacus* (the genus)! Moreover, whereas they term the guemals *Xenelaphus* on p. 297, the same animals are designated *Furcifer* on p. 78.

With the statement that the chapter on marine regions is a new feature in books of this nature, and that those by Dr. Sclater on the distribution of the various mammalian families and genera will be found of the greatest value to students, the latter half of the book must be dismissed without further notice.

A large number of figures, for the most part specially prepared for it, illustrate the volume; and to the excellence of these we are glad to be able to testify. The maps, too, which are numerous, are all that can be desired to illustrate the text. And here it may be mentioned that in the majority of instances the sub-regions are well determined, and their distinctive faunas well described. The portion of the work relating to these must, indeed, claim a high value for students. We cannot, however, but regret that the authors have not seen their way to follow Mr. W. T. Blanford in the recognition of a Tibetan sub-region, the animals of that area being of so remarkably isolated a type.

Throughout the foregoing criticisms it will be noticed that we have studiously avoided bringing forward our own views, and have been content to call attention to the discrepancies and misstatements in those of the authors. Had the authors taken more pains in bringing their subject up to date, and did they possess (if we may say so) the all-round knowledge necessary to the proper fulfilment of their task, the volume, as an expression of what we regard as somewhat old-fashioned views, might have been worthy of higher commendation than we can venture to bestow.

R. L.

## ANTIQUITIES FROM BENIN.

*Antiquities from the City of Benin, &c., in the British Museum.* By C. H. Read and O. M. Dalton. Pp. 61 + Plates 32. (London: British Museum, 1899.)

THE real interest in the finding of the Benin bronze castings centres in the fact that a negro people seem at one time to have been able to produce bronze work showing great skill in manufacture, coupled with indications of a considerable amount of knowledge of art. The question how the craft was learned immediately suggests itself. Messrs. Read and Dalton appear (p. 16) to accept the statement of the natives (p. 6) that it was introduced by the Portuguese, but further on (p. 19) they acknowledge that it is "not easy to solve how far Europe is responsible for the art of metal casting in West Africa." From what may be called internal evidence, we may reasonably suppose that some of the best castings date back to the end of the fifteenth or the beginning of the sixteenth century. If the Portuguese introduced the art we should expect that some specimens of Portuguese work of that date, and of equal merit, should be found in our museums. So far no such evidence is forthcoming. There is, however, no reason why the art should not have been in existence before the arrival of the Portuguese amongst the Bini in the same way as the domestic architecture in Benin and the surrounding country is most probably indigenous, or in the same way as the decorative art of the Ashantis is indigenous in so far as our knowledge goes. In all probability, the solution of the question will be found to lie in the fact that the existence of the art antedates the arrival of the Portuguese, who, however, may have given it considerable impetus. Yet it must not be taken for granted that the Portuguese were the only people who influenced the art, for there is plenty of evidence pointing to other influences, and we can rest assured that, amongst a people so fond of trade as the African negroes, trade objects would be numerous, and these would leave their impress behind them. For instance, an almost exact copy of a spiral bracelet from Benin was brought many years ago from Tunis, and is now in the Blackmore Museum, while its prototype is to be found at the present day on the banks of the Upper Congo.

From a time shortly subsequent to the arrival at the British Museum of the large collection of these bronze castings, the authorities prohibited any student from taking notes, on the plea that they intended to publish a work on the collection. The work is now before us. It consists of an historical introduction with a descriptive summary, for purposes of comparison, of the Yoruba gods taken from Burton instead of from Ellis's later and more comprehensive account, a chapter each on the ivory work, the metal work, the early Europeans, and on dress, ornament and weapons, as exemplified by the specimens in the collection. The illustrations are fair, but some—as, for instance, those of the ivory tusks and a king's or chief's helmet—are reproduced on too small a scale to be of much assistance to the student. It is to be regretted that the authors have limited themselves to deal solely with the specimens in the British Museum collection. The museum possesses a unique collection of the bronze castings used as historical or decorative plates on the pillars of the king's compounds, but it possesses very few of the numerous domestic and other utensils, many likewise unique, which have from time to time been on sale in London. In other words, the collection is not a representative one, as is, for instance, that of General Pitt-Rivers at Farnham. The opportunity for a comparative study of the objects *inter se* is impossible, and the student will therefore have to go to other museums to complete his studies. However, even restricted as the work is in its scope, the monograph will always be found useful, and the authors are to be congratulated on a good piece of work.

H. LING ROTH.

## THE LOST VOLUME OF HUTTON'S THEORY OF THE EARTH.

*Theory of the Earth, with Proofs and Illustrations.* In four parts. By James Hutton, M.D. and F.R.S.E. Vol. iii. Edited by Sir Archibald Geikie, D.C.L., F.R.S. (Geological Society, Burlington House, 1899.)

AS we learn from Sir Archibald Geikie in his interesting preface, the history of the later portion of James Hutton's great work on the "Theory of the Earth" is a perplexing question. In 1795 the well-known two volumes appeared, containing the first and second parts, but the title-page bears the words "in four parts." Of those two the first is little more than a reprint of the essay on the same subject read to the Royal Society of Edinburgh in 1785. The second part, dealing with the operation of natural causes on the surface of the globe—or dynamical geology, as it is now sometimes called—was new matter. These volumes are without preface or preliminary sketch, so that no clue is given to the plan of the remainder of the work, while the fact that Hutton ends his second volume with an elaborate summary suggests that he contemplated a pause of some duration before issuing the remainder. At his death, in 1797, the third volume, according to Playfair, was practically complete; and we do not know why his friends did not publish it. Perhaps, as Sir A. Geikie suggests, they waited for certain illustrations, which Mr. John Clerk, Hutton's great friend, had promised to furnish. Gaps are left for these in the text; but, at any rate, Playfair and Lord Webb Seymour quote from the manuscript in a paper on Glen Tilt, read to the Royal Society of Edinburgh in 1814. It was then lost sight of—the earlier portion, including three chapters, has vanished; the other was a parting gift from Lord Webb Seymour to Leonard Horner, and was presented by him to the Geological Society of London in 1856. In its charge it has remained, forgotten by most of the Fellows, till Sir Archibald Geikie urged its publication on the Council, promising to take upon himself the laborious task of editing. Needless to say, this has been admirably done. The manuscript is printed as though it had followed on the preceding volumes. A few small lacunæ or matters needing explanation are dealt with in explanatory notes, which are models of terseness and a great help to the reader, who, in addition, has to thank the editor for an index, not only to this volume, but also to the two others.

This fragment of a geological classic is well worth the cost of publication. Three of its six chapters are more or less controversial, and are thus, to some extent, obsolete, though it is always interesting to see how difficult problems were viewed by the greater intellects in the infancy of the science. But the other three chapters, descriptive of geological journeys in the Highlands (including the famous examination of Glen Tilt), in the Southern Uplands, and in the Isle of Arran, retain their vivacity and freshness though a full century has passed since they were penned. They also demonstrate Hutton's power as a field geologist, and thus help to refute the reproach which has sometimes been levelled at him of being a mere speculator. Besides this, they show that he could describe accurately and reason profoundly in the ordinary English tongue; and this is not the least charm in days when geological writing is apt to become a conglomerate of scientific jargon unintelligible to all but specialists. Fragment though it be, this volume has an interest and value all its own, and our best thanks are due to both the learned editor and the Council of the Geological Society, for "The Theory of the Earth" is one of the chief foundation stones of modern geology. We trust that the attention thus drawn to "Volume iii." may bring about the discovery of the manuscript which is still missing.

T. G. BONNEY.

## OUR BOOK SHELF.

*Animals in Motion. An Electro-photographic Investigation of Consecutive Phases of Progressive Movements.* By E. Muybridge. Pp. 264 + 1600 half-tone Pictures. (London: Chapman and Hall, Ltd., 1899.)

MR. MUYBRIDGE'S book, "Animals in Motion," with its numerous illustrations, offers a most interesting study, not only to the physiologist, the man of science, and to lovers of animal nature, but also to the artist and archæologist. Mr. Muybridge's attention was first directed to the movements of animals in the year 1872, while directing photographic surveys of the United States Government on the Pacific coast, by a controversy concerning animal locomotion which was being carried on in San Francisco. Mr. Muybridge tells us that according to Plato the same subject was warmly argued by the ancient Egyptians. (This statement is not verified by a reference, and it is improbable that the point is mentioned by Plato.) Mr. Muybridge determined to settle the question whether, in trotting, the horse ever had the four feet simultaneously off the ground. By an ingenious arrangement of electrically controlled cameras, Mr. Muybridge discovered and definitely proved that the trotting horse, in certain phases of his movements, has all four feet off the ground at the same time.

Mr. Muybridge became so fascinated with the new subject, namely animal locomotion, that he studied and photographed the movements of men, women, children, lions, tigers, and other animals both wild and domestic, and also the flight of birds. His book contains a series of most beautiful and interesting pictures, each illustrating some feature of movement. Of these, probably the most instructive are those of the child crawling (p. 69) and the baboon walking (p. 75). The pictures he obtained show the exact positions of the legs and feet of the animals at certain definite times. The other motions of the horse, namely the amble, the trot, the canter, the gallop, and some more, are carefully analysed by the electro-photographic method. In the fourteen series pictures of the trot, 2 and 19 (p. 107) show the four feet off the ground at the same time; these are the pictures which entirely settled the question which fortunately started Mr. Muybridge on his excellent work; the series was photographed at Palo Alto in 1879. The series on p. 229 of the mule "Ruth," bucking and kicking, show that the animal adds marked rotation of the hind-quarters to movements which, in themselves, must be terrible to the rider. In addition to the electro-photographic analysis of the movement of animals, the author devised an instrument whereby a series of pictures was recombined, and by it a life-like picture of a moving animal was projected on to a screen. The instrument is called the Zoöpraxiscope; it is in a large degree similar to the old Phenakistiscope, made by Dubosq of Paris, by means of which moving pictures were projected on to a screen at the old Polytechnic Institution ("Play-book of Science," by J. H. Pepper, 1864). From beginning to

end Mr. Muybridge's electro-photographic analysis of the movement of animals is excellent, and his results have been reproduced with great clearness of detail.

F. J. J.-S.

*Sanatoria for Consumptives in various Parts of the World.* By F. Rufenacht Walters, M.D., M.R.C.P. With an Introduction by Sir Richard Douglas Powell, Bart. Pp. 374; Illustrations 41. (London: Swan Sonnenschein and Co., Ltd., 1899.)

THIS book represents the result of a most painstaking inquiry on the part of the author into the institutions for the treatment of consumptive patients. The various sanatoria are described with a great amount of detail, more especially with regard to situation, charges, access, &c. The actual information with regard to the details of treatment is, however, scanty. Phthisical patients differ so widely *inter se* that of course anything approaching a sanatorium diary, even had it been given by Dr. Walters, would only have been of general interest. Presumably the book is intended for the professional and lay reader—both these may confidently rely upon getting much information from it with regard to the possible places for treatment; but the practitioner who intends initiating a so-called open-air treatment, of which we have heard so much and seen so little, will find considerable difficulty in getting the practical information he wants from Dr. Walters' book. He will do better to consult the earlier works of Brehmer and Jaruntowsky. Those, however, who want to build a sanatorium will do well to thoroughly master Dr. Walters' book, and especially the plates which he gives of the most known sanatoria abroad.

The book will doubtless be a surprise to many English professional readers, who probably have no idea to what an extent the sanatorium treatment has progressed abroad, and especially in Germany. It will probably also have a very wide sphere of usefulness in showing the physician where he can have his patient treated at most moderate cost in the most enlightened manner. No one can doubt that the best advice which at present could possibly be given to many phthisical patients only scantily endowed with this world's goods would be to go to such a place, for instance, as Görbersdorf, where, for from 2*l.* to 4*l.* per week they can have everything they can possibly want—a skilled and patient doctor, suitable food, climate, and accommodation. By indicating clearly the relative merits of such institutions, Dr. Walters has performed a service for which the medical profession ought to be grateful.

F. W. T.

*Measurement and Weighing.* By E. Edser, A.R.C.S. Pp. vi + 111. (London: Chapman and Hall, 1899.)

THIS small manual is intended as a guide for teachers engaged in instructing classes of young students in the first principles of practical physics. As the author states in the preface, only a limited field has been chosen for consideration, and this has been intentionally treated with more than the usual amount of detail. This has been done with the object of showing, from more than one point of view, the applications of the various principles involved.

In Chapter i., "Linear and Angular Measurements," the pupil is led from the actual copying of a standard scale to the different uses of it in determining the dimensions of various objects, first approximately, then as accurately as possible. Most of the experiments in this chapter are original and, although simple, are evidently calculated to induce thought in their working out. Chapter ii. deals with "Superficial and Solid Measurements," introducing the usual problems of mensuration in a practical manner.

In Chapter iii., after describing the trigonometrical functions and ratios, the author gives a very ingenious and novel method of graphically determining the logarithms of numbers, by means of which the student can make himself independent of tables.

The concluding chapter consists of a very clear and detailed experimental exposition of the principles relating to "Mass and Density."

The system adopted has been actually followed in class teaching, and will no doubt be helpful to others in the arrangement of their experimental courses.

*Die physikalischen Erscheinungen und Kräfte.* By Prof. Dr. Leo Grunmach. Pp. viii + 442. (Leipzig: Otto Spamer, 1899.)

IN this volume the author brings before the reader a popular and accurate account of the greater number of physical phenomena and forces which are more or less commonly met with in every-day life. The book is intended for those readers who wish to gain a general insight into common physical matters and phenomena without being troubled with a too detailed account which would necessitate a more minute study.

Commencing with the definitions and means of determining mass and measurements, the author successively deals with the principles involved in and phenomena connected with sound, light, heat, magnetism, electricity, &c., concluding with most of the more recent discoveries, such as Röntgen rays and Marconi's system of telegraphy.

The contents of the book are far too numerous for us to deal with in a few words, so we must be content to point out that the text is profusely illustrated with well-chosen woodcuts, a special feature being a set of portraits of notable scientific men. We may mention here that on p. 143, in the chapter on spectrum analysis, it was intended to give the portrait of Sir Norman Lockyer; but although the illustration is coupled with his name, the portrait is that of Sir William Flower.

Not only should the book be read by those who wish to know something about natural phenomena and forces, but it should be useful to students who desire to make themselves acquainted with the German language.

*Practical Plane and Solid Geometry (Test Papers).* By George Grace, B.Sc., A.R.C.S. (London: Macmillan and Co., 1899.)

THIS publication consists of a series of twenty-four graduated test papers selected chiefly from the annual examination questions in the elementary stage of geometry of the Science and Art Department. Each exercise contains six problems, and being printed on cartridge paper the solutions may be worked out directly on the sheets under their respective headings. This feature should be specially commendable to teachers of large classes, as the uniformity of the arrangement of the questions and the size of the sheets will be found of considerable help from an examiner's point of view.

*Practical Dictionary of Electrical Engineering and Chemistry in German, English and Spanish.* By Paul Heyne, assisted by Dr. E. Sanchez-Rosal. Vol. II. English-Spanish-German. Pp. vii + 209. (Dresden: Gerhard Kühtmann. London: H. Grevel and Co., 1899.)

THE difficult task of preparing a technical trilingual dictionary has been accomplished in the present case with commendable accuracy. The Spanish and German equivalents are given of a large number of technical terms used in engineering, modern machine industry, metallurgy, electricity and chemistry, and other applied sciences. To the engineer, the student of physical science, and the commercial man, the dictionary should prove of great service.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### Magnetic Strain in Bismuth.

YOUR report of the meeting of the Royal Society of Edinburgh, held on May 16 (NATURE, June 22, p. 192), states that Dr. C. G. Knott has obtained a slight indication that there is a change of form in bismuth when strongly magnetised.

In the *Phil. Trans.*, vol. clxxix. (1888) A, p. 216, I described an experiment in which a rod of bismuth was found to exhibit an elongation of about 1·5 ten-millionths of its length in a magnetic field of 840 C.G.S. units. As to the reality of this effect and the fact that it was due solely to magnetism, there was no doubt whatever.

Since the publication of my paper I have repeated the experiment with another sample of bismuth obtained from Messrs. Johnson and Matthey; but though the field was brought up to nearly 1500 units, there was never the smallest indication of any magnetic change of length. An elongation one-tenth as great as that observed in the former case would have been easily perceptible.

After this experience I should hesitate to attach importance to any such observations unless the bismuth employed had been proved by analysis to be free from traces of magnetisable metals.

SHELFORD BIDWELL.

———

MY experiments were made with a bismuth *tube*, the notion being that, as in like experiments with nickel tubes, any existing strain would be much more easily detected by means of secondary volume changes than by means of the direct elongation measurements which Mr. Bidwell so successfully carried out. Mr. Bidwell's warning as to the necessity of having the material pure is well-timed. So far I have taken no special precautions in this direction; but in the improved form in which I purpose repeating the experiment, and from which I hope to get some really decisive result, this question of freedom from traces of strongly magnetic metals must of course be carefully considered.

C. G. KNOTT.

### Gooseberry Saw-fly.

I SHALL be obliged if any reader of NATURE who has happened to pay attention to the gooseberry saw-fly will let me know whether my experience agrees with that of observers in other parts of the country. In Yorkshire the larvæ were so abundant in 1893, 1894 and 1895, that the bushes were in many places stripped of their leaves every summer. In 1896, there was a marked diminution, and many of the larvæ contained ichneumons. In 1897, 1898 and 1899, they have been so scarce that I have had difficulty in getting specimens for anatomical study.

L. C. MIALL.

The Yorkshire College, Leeds, June 29.

### School Laboratory Plans.

REFERRING to Mr. Richardson's letter (p. 199), our laboratory, now approaching completion, will afford, as regards chemistry in a room 30 by 26 feet, accommodation for twenty-seven boys, including one 18-foot bench for general purposes, and two draught cupboards. We have one 21-foot wall bench and two 18-foot double central benches in parallel, and one 10-foot wall bench at right angles. I believe a novel feature to be the demonstrator's platform placed on the top of and slung across the central benches, provided with a revolving chair and a table, and approached by steps. The whole sacrifices two working places only. The demonstrator has sixteen boys in front of him, five parallel with him, and six behind him, at a maximum distance of fifteen feet. His commanding position should save considerable time usually spent in running about. A large mirror might further aid matters. The central benches alone have reagent shelves.

A. E. MUNBY.

Felsted School, Essex.

## ILLUSTRATIONS OF MIMICRY AND COMMON WARNING COLOURS IN BUTTERFLIES.

AN interesting, though brief, paper entitled "Natural Selection in the Lepidoptera" was read by Mr. Mark L. Sykes before the Manchester Microscopical Society on November 4, 1897, and published in the *Transactions* for the year (p. 54). The chief interest of the paper consists, as the author points out, in the eight excellent plates by which it is accompanied. These plates contain a very large number of figures reproduced by a photo-mechanical process from the insects themselves. The author has evidently had at his disposal a very large and complete collection, and having selected a number of very fine illustrations he thus makes them available for all other naturalists.

At the opening of his paper the writer expresses some doubt as to whether the subject is a suitable one for a Microscopical Society; but on this question there need be no hesitation. The microscope is an instrument of the most varied uses, and is necessary in the investigation of this subject among others, for without its aid we cannot ascertain the depth to which mimetic resemblance penetrates into the structure of organisms. The interpretation of these resemblances as due to natural selection implies that they are confined to visible effects, and therefore the microscope should reveal an underlying difference beneath the superficial similarity. Hence a paper which, by describing this fascinating subject, and abundantly illustrating it, directs attention to a promising field for microscopic inquiry, is in every way suitable for the audience before which it was read, and the Manchester Society is to be congratulated upon the broad view it has taken of its subject and responsibilities. The present writer has already commenced the study of mimetic resemblance from this point of view, and has found that the methods by which the transparency which is necessary for the likeness attained in a group of Lepidoptera from South America differ in the most marked degree, although the superficial resemblance is of a very high order (*Journ. Linn. Soc.*, vol. xxvi., 1898, pp. 596–602; plates 42, 43, 44).

The great interest of Mr. Sykes' paper is the abundant illustration which it provides for the two different classes of resemblance often confused together under the name of "Mimicry." A few words on the history of the recognition and suggested explanation of these two classes may be useful, inasmuch as great confusion still exists upon the subject. The theory of mimicry was first suggested by H. W. Bates in his important paper published in the *Transactions* of the Linnean Society for 1862 (vol. xxiii.). He here suggested the idea of a conspicuous, abundant, and specially defended species, serving as the model towards which other comparatively rare and defenceless species are brought by natural selection. His illustrations were taken from the fauna of tropical America, and the explanation was suggested to him by the study of his collection after his return home from his prolonged visit to the Amazon Valley. The theory is of special interest, as it was probably the first great result of the theory of natural selection after its appearance in the *Journal* of the Linnean Society in 1858, and in the "Origin of Species" in 1859. Bates' generalisation was extended by A. R. Wallace to the tropical East (*Trans. Linn. Soc.*, 1866, vol. xxv.), and by Roland Trimen to Africa (*Trans. Linn. Soc.*, 1870, vol. xxxi.). In the first-named paper Bates expressly pointed out that his explanation did not cover all cases of mimetic resemblance, but that there were a very large number of species abundant in individuals, and presumably specially defended, which nevertheless "mimic" each other. Furthermore, this kind of resemblance is as close and detailed as that which the Batesian theory of mimicry sought to explain. For such

cases Bates could only suggest—and Wallace at first accepted the suggestion—that the likeness was produced by some unknown influence connected with locality. In some mysterious way the species were supposed to be made alike as a direct result of life in a common district. No further advance was made until 1879, when Fritz Müller suggested (*Kosmos*, May 1879, p. 100) that the resemblance between relatively unpalatable forms was advantageous in facilitating the education of their young and inexperienced enemies, thus preserving a large proportion of the individuals which would have been necessarily sacrificed if the "warning" pattern of each species were different from that of every other in the same locality. Prof. Meldola translated this paper (*Proc. Ent. Soc.*, Lond., 1879, p. xx.) and argued in favour of the explanation which Wallace also accepted. The same kind of likeness between specially protected forms was shown to exist in the tropical East by F. Moore (*Proc. Zool. Soc.*, 1883), and in Africa by the present writer (Report Brit. Association, 1897, p. 688).

The hypothesis associated with the name of H. W. Bates was believed by a large number of naturalists from the very first, while that due to Fritz Müller was a long time in making its way. Of recent years, however, it has come to the front, chiefly in consequence of the papers of F. A. Dixey (*Trans. Ent. Soc.*, Lond., 1894, 1896, 1897). In these papers Dixey has shown strong reasons for the belief that many examples formerly explained by the theory of Bates are in reality to be interpreted by that of Fritz Müller. The wonderful tropical American groups of remotely allied species with a common appearance, selected by W. F. H. Blandford, assisted by the late Osbert Salvin, from the great Godman-Salvin collection, and exhibited at the Royal Society (1896) and Entomological Society (1897), also tended to deepen the impression which the Müllerian theory was making. It was clear to every one who examined the various groups (lists of the species exhibited are given in *Proc. Ent. Soc.*, Lond., 1897) that the vast majority of the likenesses were between species which are known to be abundant and believed to be relatively unpalatable.

The great interest and value of Mr. Sykes' paper is given by the eight excellent plates which accompany it, reproducing many examples of Müllerian mimicry, and large numbers which are believed by the author and many others also to be still explicable by the theory of Bates. Their full discussion, as far as the facts at present known will allow, would be of great interest and would, in the opinion of the present writer, lead to the conclusion that a considerable proportion, at least, are more probably to be explained on Müllerian lines. The examples in the first two plates are almost without exception admitted to fall under the Müllerian theory, and they are described as "Mutual Protective Resemblance of Inedible Butterflies." All the examples are selected from tropical America, and supply a permanent record of many of the members of the groups selected by Blandford.

Plate II. is here reproduced, and will serve well to show the closeness of the likeness which is attained, as well as the composite nature of the groups. That containing Figures 6 to 10 is the most interesting in this respect, containing as it does representatives from three distinct sub-families, all of which are believed to be unpalatable—the *Danainae*, *Ithomiinae* and *Heliconinae*. A few errors which have crept into the description of the figures have been set right in the present reprint. (Fig. 6 is that of *Heliconius telchinia*, not of *Eueides zorcaon*; *Eresia*, Fig. 15, belongs to the *Nymphalinae*, not the *Pierinae*.) The distinction between the *Ithomiinae* and *Danainae* is now generally recognised, and has been introduced. A few of the species, viz. those named in Figs. 3, 4, 11, 14, 15, 19, and 20, are insufficiently represented or altogether absent from the collection with which the plate has been compared. Hence the present writer cannot feel confident that these identifications are correct.

In the third plate the well-known resemblance between the three forms of female of *Hypolimnas misippus* (*Nymphalinae*), with its very different male, and the three forms of *Limnas chrysippus* (*Danainae*) are well shown by many examples; but the author has fallen into the error which has often been made before (among others by the present writer), of stating (p. 61) that the forms completely correspond in the various parts of their range. The following statement is, it is believed, all that we are justified in making. In the tropical East (India, &c.), *Limnas chrysippus* is rarely represented by any but the typical forms, with amber ground colour, paler than in Africa, and black and white tip to the fore-wings; the form with white hind-wings (*alcippoides*) is rare, and that without the black and white tip (*klugii*) much rarer still. On the other hand, the two latter forms of the mimicing female are not uncommon, especially the latter. At Aden all three forms of both model and mimic occur together commonly. In North-east Africa the chief forms of the Danaine are the normal and the *klugii*, the white-winged form also occurring more rarely. In Somaliland the *klugii* form seems to predominate; out of several dozen specimens presented to the Oxford Museum by Mr. C. V. A. Peel, and captured in two visits, not a single form except *klugii* is present. The few female *H. misippus*, on the other hand, are normal, and so a marked want of correspondence is revealed. Passing down the east of Africa to the south, *klugii*, at first abundant, becomes gradually rarer, until in the south it is extremely rare. In the female *misippus*, on the other hand, the form *inaria*, resembling *klugii*, is commonly intermingled with the typical form right down to the south. The white-hind-winged form of both model and mimic have a more parallel development occurring not uncommonly in both species. In tropical West Africa, on the contrary, the Danaine butterfly is always white-hind-winged, and the size of the white area is large (constituting true *alcippus*), while the very few females of *H. misippus* which I have seen from this part of the world were normal. Much more evidence is required before the relationship can be made out for all parts of the extremely wide range which these two species have in common. I have here set down the conclusions which seem to be warranted by the facts at present known, in the hope that others may be induced to publish, or at least to make their observations known to the present writer.

To summarise the facts set forth above, the varieties of *Limnas chrysippus* are more definitely restricted to certain localities than those of the female *Hypolimnas*, which is in all localities apt to be a more variable insect; furthermore, intermediate forms between the varieties are commoner in the latter than in the former. In the case of those localities where there is a marked restriction of the forms of *chrysippus* (Somaliland and tropical West Africa), there is no evidence of any equal restriction of the varieties of its mimic.

The figure of a white-hind-winged *alcippus*-like female *Hypolimnas* from Sierra Leone (Fig. 8) appears to have been taken from a not very perfect drawing, while all the other figures on all the plates are excellent reproductions from the specimens themselves.

In the brief but useful memoir which accompanies these plates, the principles of mimicry are described, and many of the figured examples alluded to. In describing the distribution of the varieties of *Limnas chrysippus* which has been here summarised, the author states that the uniformly coloured *dorippus* (*klugii*) is supposed to be the ancestral form. The immensely predominant mimicry of the type form by butterflies and moths belonging to all kinds of remotely allied groups, would, however, indicate with tolerable certainty that the type

form is the ancestral one, just as the conclusion that Africa is the ancestral home of the species is justified by the predominant amount of mimicry of which *D. chrysippus* has been the attractive centre in this as compared with all other parts of its vast range. The time which would be necessary to bring about so deep an impression on so many diverse members of the surrounding insect fauna, justifies the view that the type form has persisted as it is for a very long period, and that it is an extremely ancient inhabitant of the country in which, far beyond all others, these effects are marked.

The statement on p. 61, that the varieties of the female *Hypolimnas misippus* are nowhere found "where the inedible *chrysippus* and its varieties do not occur," is an error. For many years now—certainly between twenty and thirty—the former species has been established in some of the West Indian islands and certain parts of tropical South America.

There are several errors in the spelling of names of species, and the figures in the plates are often wrongly sexed and sometimes wrongly named in the descriptions.

The doubtful points in the paper have been here discussed at some length, and errors of detail pointed out; but the present writer would wish in conclusion again to emphasise the interest of this short communication, and again to draw attention to the usefulness of the numerous illustrations. E. B. P.

## THE UNITED STATES NATIONAL MUSEUM.[1]

THE last report issued by the U.S. National Museum furnishes abundant evidence of the energy with which America is now conducting scientific inquiry, and of the zeal with which she is augmenting the rich and varied collections preserved at Washington. Like most collections of the same character, the National Museum owes its origin to the generosity and enterprise of private individuals; and it was only after some years of precarious existence that it obtained due assistance and recognition from the State. The society organised in 1840, and called the "National Institute," may perhaps be regarded as the parent of the present Museum. Though prosperous during the first few years of its existence, it failed to interest a wide body of the public, and it was reserved for the Smithsonian Institution to obtain official recognition as the only lawful place of deposit for the national scientific collections. In 1846 such recognition was accorded by Act of Congress, and from that year until the present time the work of collecting and exhibiting new material has been carried on without interruption.

One striking characteristic which distinguishes the National Museum from similar institutions in other countries is to be found in the somewhat restricted area to which it has confined its attentions. While the museums of Europe include exhibits from all regions of the globe, the United States collections are, with a few exceptions, exclusively North American. The advantage of so restricting the area of research is obvious, for by this means the Museum has been enabled to attain an unrivalled completeness in the departments of science to which its energies have been devoted. The authorities have also found considerable assistance in the fact that for nearly twenty years they have received all collections of minerals and objects bearing on natural history archæology and ethnology which have been made during the numerous surveys undertaken by the Government of the United States.

The present report occupies over eleven hundred pages, and it would be impossible in a short notice to do more than sketch the general nature of its contents, and to indicate the sections into which it naturally falls. The volume is divided into two unequal parts, of which the first consists of the report of the late Mr. Brown Goode, assistant secretary of the Smithsonian Institution, to which are attached a number of appendices. This report covers the whole ground of the Museum's activities, describing new accessions, the arrangement and labelling of the collections, the work of exploration conducted during the year, the official publications and contributions made to scientific literature, and the work done in connection with visitors and students at the Museum. These general summaries are followed by detailed reports of the work done in the various scientific departments, concluding with the report of the administration department of the Museum. After a perusal of these reports it is evident that, in addition to prosecuting scientific inquiry, the Museum is doing much to render its resources available to the public at large. By its system of exchange and its distribution of duplicate specimens, a large number of local museums in the United States have benefited in the course of the year.

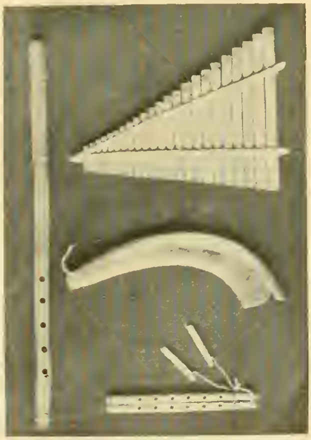

FIG. 1.—Wind Musical Instruments. 1, Reeds or Pan Pipes; 2, Ram's Horn; 3, Double Flute; 4, Flute.

The second and larger portion of the volume is of greater general interest, for it consists of a number of original papers describing and illustrating the collections preserved in the Museum. Of these, perhaps the most important is the paper on "Prehistoric Art" by Mr. Thomas Wilson, the curator of the Division of Prehistoric Archæology. Although in the main describing the specimens under his charge, Mr. Wilson has not confined himself to the art of primitive America, but has given a very exhaustive sketch of the products of early civilisations all over the world, and his essay forms a valuable contribution to the study of prehistoric man. Another interesting paper devoted to a special subject is contributed by Mr. Walter Hough, the assistant curator of the Division of Ethnology, who has written a monograph on "The Lamp of the Eskimo." The Museum possesses a very complete collection of Eskimo lamps, comprising examples used by nearly every tribe from Labrador to the Aleutian Islands. The lamps are

[1] Report of the United States National Museum under the direction of the Smithsonian Institution, for the year ending June 30, 1896. Pp. xxiv + 1107. (Washington: Government Printing Office, 1898.)

classified according to their *provenance*, and full descriptions and illustrations are given of a large number of typical examples.

Two other papers in the volume deserve special mention, as they illustrate another side of the Museum's activities. In addition to their purely scientific work,

FIG. 2.—Colossal Statue of the God Hadad, Gertchin, Northern Syria.

special attention is now being given by its officers to the function of the Museum as an educational institution, and to the popularisation of the collections. At the International Exposition held at Atalanta in 1895, special collections were organised and arranged for the illustration of distinct subjects of study, and the descriptions that were published at the time are here reprinted as a record of the collections that were shown. Of these papers, that on "Biblical Antiquities" is written by Dr. Cyrus Adler and Dr. Cassanowitz, who describe a number of exhibits illustrating the geology, flora and fauna of Palestine, while other exhibits dating from ancient as well as modern times throw valuable light on the text of the Old Testament narratives; one of the plates, for instance, which is here reproduced, is intended to illustrate some of the wind instruments mentioned in the Bible (Fig. 1). Moreover, by means of a fine series of casts, reproduced by photography, the antiquities of Western Asia during the principal periods of Old Testament history are fully represented. Two good specimens of these are here given—a colossal statue of the god Hadad from Northern Syria (Fig. 2), and a bas-relief of a lion chase in the so-called "Hittite" style (Fig. 3), which exhibits many interesting points of resemblance to its Assyrian prototypes. The other paper deals with "Chess and Playing Cards," and consists of a catalogue of games and implements of divination, which were also exhibited at Atalanta. This collection was formed by the Museum in collaboration with the University of Pennsylvania, and it is here described by Mr. Stewart Culin, the director of the Museum of Archæology and Palæontology in that University. We have not done more than indicate the varied nature of the contents of this report, but sufficient has been said to show that the study of science and archæology in the United States is receiving valuable encouragement from the Government, and that the system and methods there adopted compare very favourably with those in many European museums.

## *AN IMPROVED LIQUID INTERRUPTER FOR INDUCTION COILS.*

THE following is a description of an improved form of Wehnelt-Caldwell interrupter for induction coils, devised by the writer in conjunction with Mr. J. C. M. Stanton and Mr. H. Tyson Wolff.

The two electrodes of sheet lead C and D dip into dilute sulphuric acid, contained in the glass vessel A. The electrodes are separated by a hollow glass or porcelain cylinder B, which surrounds the electrode C. This cylinder is closed at the bottom with the exception of a circular aperture E, about three or four millimetres in diameter. Through this aperture projects the small end of the conical glass or porcelain valve F, which by means of the screwed carrier tube H and the milled nut G, can be raised or lowered so as to open or close the aperture to any desired extent. As when the apparatus is at work

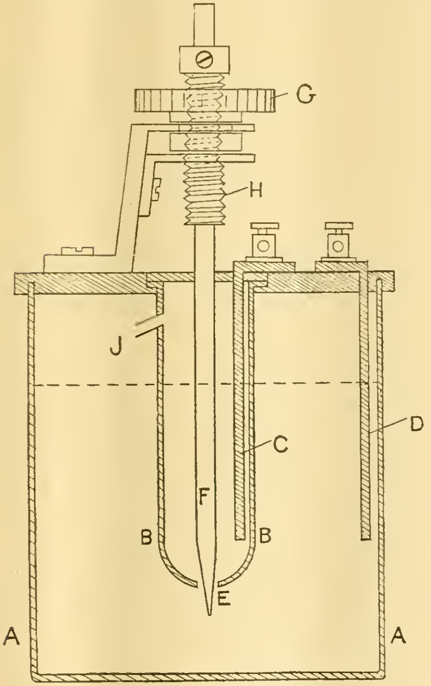
FIG. 3.—Hittite Lion Chase.

the liquid is found to rise in the cylinder B, the latter is provided with an overflow at J.

The interruptions take place in the valve aperture, and appear to be due to the formation of gas or steam therein. The extent to which the valve is open or shut determines the amount of current passed, and the

frequency within wide limits. The wider the valve is open the larger is the current, and the lower is the frequency, and *vice versâ*. With this apparatus in circuit with a 10-inch coil connected direct on to the 100-volt supply mains, it was found that by adjusting the valve the primary current could be altered from 0 to 25 amperes, while the pitch of the sound of the discharge could be changed from a very shrill whistle down to a rattling roar. By introducing additional self-induction into the circuit the frequency can be lowered still further.

The direction of the current through the apparatus does not affect the results, and the arrangement, when suitably adjusted, works well with alternating current, the sparks in each direction being of equal power. The troublesome fatigue phenomena to which the Wehnelt



instrument is liable appear to be absent, while the difficulties as to the fusing of the platinum wire and the cracking of its insulating sheath are also avoided. This improved instrument has in fact all the advantages of that of Caldwell, of which it is a modification, with the further advantage of easy adjustment to suit different voltages, and to give different amounts of power and different frequencies. A. A. CAMPBELL SWINTON.

## THE SEVENTH INTERNATIONAL GEOGRAPHICAL CONGRESS.

AT the meeting of the sixth International Geographical Congress in London in 1895, it was decided that the seventh should take place in Berlin in 1899. The Berlin Geographical Society, according to the precedent of previous Congresses, undertook the necessary arrangements, and these have now been perfected. The Congress will differ from that of London by the absence of a geographical exhibition, and by the more thorough organisation of scientific excursions under specialist leaders before and after the meeting.

The proceedings will commence informally by an evening gathering on Wednesday, September 27, when an opportunity will be afforded for conversation amongst the members. Next day the formal opening of the Congress will take place in the splendid new buildings of the Prussian House of Representatives, which has been generously placed at the disposal of the Congress for the whole meeting. As in London, the proceedings of each day will include a forenoon sitting for the discussion of papers of general interest, and several sectional meetings in the afternoon for subjects which appeal to a limited number of specialists.

The Bureau of the Sixth Congress (of which Sir Clements Markham is President and Dr. Scott Keltie and Dr. H. R. Mill Honorary Secretaries) will present a report and resign its functions to that of the new Congress, the President of which is Baron von Richthofen and the Secretary Hauptmann Kollm. The various committees of the seventh Congress, honorary and executive, bear the names of the most distinguished geographers of all countries, and the gathering promises to be a really representative one.

The papers which have been promised are grouped into seven main divisions, viz. mathematical geography, physical geography, biogeography, anthropogeography, exploration, historical geography, and geographical education. The papers will be very numerous, but as a strict time limit of twenty minutes is to be enforced, there will be an opportunity for effective discussion.

Some of the most interesting subjects to be dealt with in the first group are the position of mean sea-level, the present state of research on the tides, and seismology, while in physical geography Prof. W. M. Davis and Prof. de Lapparent will deal with questions of geomorphology, and oceanography will be treated in great detail in conjunction with polar research.

Dr. Nansen, Sir John Murray, the Prince of Monaco, Prof. Chun (of the *Valdivia* expedition), Profs. Pettersson, Thoulet, &c., have all promised to take part. The plans of the German Antarctic expedition will be explained by Dr. von Drygalski, the chosen leader; while Sir Clements Markham and Sir John Murray will give an account of the progress of the arrangements of the British Antarctic expedition. It is hoped that a general scheme may be agreed upon for simultaneous and strictly comparable observations, so that by combined action the two expeditions will secure the maximum result for their labours.

The distribution of plants will be dealt with by Profs. Engler, Drude and others, while numerous papers on other branches of physical geography are promised.

Under the head of "Exploration," the names of several Germans are announced, but no British subjects have come forward to claim international importance for their journeys.

One feature of the Congress which promises a practical outcome is the prominence which is given to questions of nomenclature. Prof. Richter (of Graz) will propose a systematic terminology for use in research on glaciers; and the terminology and nomenclature of the forms of the ocean floor will be discussed by Profs. Wagner, Krümmel, Voiekoff, and Dr. H. R. Mill. Proposals for the uniform use of the metric system and the centigrade temperature scale in all geographical work will also be put forward.

The scientific excursions, which for the most part precede the meeting of the Congress, have been well organised. The programme has just been issued, giving particulars as to route, leaders, terms, &c., and also containing a list of the best maps and guide-books, and a

bibliography of the scientific literature bearing on each excursion. Most of the excursions start late enough to allow members who have been present at the British Association meeting at Dover to attend them, and they all terminate at Berlin in time for the feast of welcome. They are as follows:—

(1) Siebengebirge, Rhine, Eifel, Moselle, from September 19 to 25, under the guidance of Prof. Bonn and Drs. Philippson and Kaiser.

(2) Taunus, Rhine, Nahe, Lahn, from September 21 to 26, conducted by Prof. Sievers, of Giessen.

(3) The Vosges, from September 21 to 25, led by Profs. Gerland and Weigand, starting from Strassburg.

(4) Thuringia, from September 23 to 27, conducted by Profs. Walther and Regel.

(5) The Island of Rügen, from September 22 to 27, starting from Greifswald, led by Profs. Credner, Cohen, and Deecke.

(6) East and West Prussia, starting from Königsberg, and led by Profs. Jentzsch and Conwentz, from September 22 to 27.

(7) Glacial excursions in the North German Plain will be made to Rüdersdorf, near Berlin, on October 1, and from Hamburg along the Baltic shores, from October 7 to 11, under the charge of Prof. Wahnschaffe and Drs. Keilhack and Müller.

All communications as to the Congress or the excursions should be addressed to "The Seventh International Geographical Congress, 90 Zimmerstrasse, Berlin, S.W."

## *SCIENCE AT THE WOMEN'S INTERNATIONAL CONGRESS.*

THE Science Section of the Women's Congress was held at the Small Hall in the Westminster Town Hall on Thursday, June 29, with Mrs. Ayrton in the chair, in the presence of a large and attentive audience. The proceedings were divided into two classes—the work of women in the physical sciences, and the work for women in the biological sciences. Astronomy was represented by Mlle. Klumpke, head of one of the departments at the Paris Observatory; geology by Miss Raisin, of Bedford College; chemistry by Miss Dorothy Marshall, of Girton College; bacteriology by Mrs. Percy Frankland; and botany and zoology by Miss Ethel Sargant. The work already accomplished by women in these various branches of science was dealt with by most of the speakers, as also the openings for women who desire to take up science as a profession. Mrs. Ayrton, in the course of her interesting and able address, pointed out that there was an important outlet for the work of women at the present time in the manufacture of electrical apparatus, the demand for electrical instruments being so great that manufacturers were not able to cope with it, and an opportunity was now offered for women with the necessary education, energy and capital to start a factory for this purpose. The subject of research work was also discussed, and stress was laid upon the fact that, inasmuch as the majority of students who take up science do so either as an avenue to a degree or with the idea of earning a livelihood by teaching later on, their training was as a rule insufficient and quite inadequate to permit them to undertake independent original work; whilst on the other hand the demands upon their time made by teaching was so great as to leave practically no leisure for higher work, even when they were qualified to do it. Until this condition of things is altered, and until more women are attracted towards science for its own sake, and not as a means to an end, the contribution of women in the shape of original work must necessarily be limited. It was highly satisfactory to find that, in the open discussion which followed, an attempt on the part of two speakers to introduce the question of vivisection from the anti-vivisectionist point of view was not tolerated by the audience, these speakers being refused a hearing. It is not too much to say that the papers contributed were worthy both of their subjects and their authors, and that there was a refreshing absence of the hackneyed comparison of the relative position and intellectual powers of men and women, which has been such a favourite theme with so many speakers at this Congress. The next International Congress of Women will be held five years hence in Berlin.

## *NOTES.*

WE notice with much regret the announcement that Sir William H. Flower, K.C.B., F.R.S., late Director of the Natural History Departments of the British Museum, died on Saturday, July 1.

THE Albert Medal of the Society of Arts for the present year has been awarded by the President and Council to Sir William Crookes, F.R.S., "for his extensive and laborious researches in chemistry and in physics, researches which have, in many instances, developed into useful and practical applications in the arts and manufactures." The Swiney Prize, awarded every fifth year for a work on jurisprudence, has been awarded to Dr. Dixon Mann for his book on "Forensic Medicine and Toxicology."

AT the annual meeting of the Société nationale d'Acclimatation de France the Isidore Geoffroy Saint-Hilaire Grand Silver Medal was awarded to Prof. J. Cossar Ewart, of the University of Edinburgh, for his zebra hybrid work, and to Miss Eleanor A. Ormerod for her work in entomology.

PROF. MOISSAN has been elected a foreign member of the German Electro-chemical Society.

THE Premier of Queensland has announced that he intends to ask the Queensland Parliament to grant 1000*l.* in aid of the proposed Antarctic exploration expedition.

A CIVIL List Pension of 60*l.* per annum has been granted to Mrs. Kanthack "in consideration of the eminent services rendered to science by her late husband, Dr. A. A. Kanthack, professor of pathology in Cambridge University."

AT Berlin, on June 27, Prof. Virchow opened the new pathological museum which bears his name and has been built under his superintendence. It has cost about 560,000 marks, and contains a collection of more than 20,000 specimens, collected almost wholly by Prof. Virchow himself, and representing the history of pathology during the past half-century.

WE learn from *Science* that Mr. Secretary Long has appointed a Board of Visitors to examine and report upon the U.S. Naval Observatory, to consist of Mr. Wm. E. Chandler, Mr. Alston G. Dayton, Prof. Geo. C. Comstock, Prof. Geo. E. Hale, and Prof. Edward C. Pickering.

THE prize of 500 guineas, offered by the Sulphate of Ammonia Committee for the best essay on "the utility of sulphate of ammonia in agriculture," has been awarded by the judges—Mr. J. Bowen-Jones, of Shrewsbury, and Dr. J. Augustus Voelcker, of London—to Mr. James Muir, formerly professor at the Royal Agricultural College, Cirencester; subsequently at the Yorkshire College, Leeds; now County Instructor in Agriculture to the Somerset County Council. Seventy-three essays were sent in.

WE learn from the *Lancet* that the Senatus Academicus of the Clark University, Worcester, Massachusetts, which is about to commemorate the anniversary of its foundation, has invited

Prof. Angelo Mosso to deliver a lecture on a subject specially chosen for the occasion, and dealing with a scientific problem of present and universal interest, and Italy, to judge from her leading organs, professional and lay, is deeply sensible of the honour. Prof. Mosso started for the United States on June 20, and has chosen as his theme "I Processi Psichici ed il Movimento" (the Psychic Processes and Movement).

THE death is announced of Mr. Henry Wollaston Blake, F.R.S., at eighty-four years of age. Mr. Blake was an original member of the Institution of Civil Engineers, of the Institution of Mechanical Engineers, and of the British Association. He was elected a Fellow of the Royal Society in 1843.

THE forty-eighth meeting of the American Association for the Advancement of Science will be held at Columbus, Ohio, on August 21-26, under the presidency of Prof. Edward Orton. The first general session will as usual be held on Monday morning, August 21, when the president-elect will be introduced by the retiring president, Prof. F. W. Putnam, and addresses of welcome will be made by the Governor of Ohio and the Mayor of Columbus. The addresses of the vice-presidents will be given on Monday afternoon, and the address of the retiring president in the evening. The several sections will meet as usual during the week, and Saturday will be devoted to an excursion, probably to the mounds at Fort Ancient, the coal mines in Hocking Valley, and the natural-gas fields. Further information may be obtained from the permanent secretary of the Association, Dr. L. O. Howard, Cosmos Club, Washington, D.C., and from the local secretary, Prof. B. F. Thomas, Ohio State University.

THE annual general meeting of the Marine Biological Association was held in the rooms of the Royal Society on June 28. The president, Prof. E. Ray Lankester, F.R.S., occupied the chair. The Council reported that the laboratory at Plymouth continued in a state of efficiency, and was adequately equipped with the most modern requirements for marine biological research. The investigation of the natural history of the mackerel, commenced last year by Mr. Garstang, had been continued, and a report on the variations, races and migrations of this fish had been published. A systematic study of the physical and biological conditions prevailing in the waters at the mouth of the English Channel had also been commenced, which it was hoped would throw light on the causes which determine the movements of migratory fishes. The examination of the fauna and bottom deposits between the Eddystone and Start Point had been concluded by Mr. Allen, the director of the laboratory, and a report on the subject had appeared in the *Journal* of the Association. Seventeen naturalists and eleven students had worked in the laboratory, in addition to the members of the regular staff. The following were elected members of Council for the year:—President, Prof. E. Ray Lankester; hon. treasurer, J. A. Travers; hon. secretary, E. J. Allen; Council, F. E. Beddard, Prof. F. Jeffrey Bell, G. P. Bidder, G. C. Bourne, G. H. Fowler, S. F. Harmer, Prof. W. A. Herdman, Prof. S. J. Hickson, Prof. T. Johnson, J. J. Lister, D. H. Scott, Prof. C. Stewart, Prof. D'Arcy Thompson, Prof. W. F. R. Weldon.

IT is the opinion of many meteorologists that daily telegraphic reports from Iceland would be of inestimable value in weather predictions for Great Britain and northern Europe. The commercial intercourse with Iceland would, however, evidently not pay the interest on the cost of the cable, and it is only quite lately that the Danish meteorologists have received from business men a proposition, already mentioned in these columns, that makes the project seem at all feasible. The proposition is referred to by Prof. Cleveland Abbe in the *Monthly Weather Review*. It is as follows:—The "Grande Compagnie des Télégraphes du Nord," having its centre at Copenhagen, has undertaken to build and to maintain a line from Shetland, touching the Faroe Islands and ending at Iceland, if an annual revenue of 13,500*l*. is guaranteed for the first twenty years only. The Government of Denmark and Iceland will establish and maintain the meteorological stations and the expense of daily telegraphic bulletins, and will perform the hydrographic work necessary in connection with the laying of the cable, and will also guarantee an annual subvention of 5000*l*. for twenty years. Therefore, all that now remains to be done in order to secure telegraphic communication with Iceland for commercial and meteorological purposes is to secure the remaining annual income of 8500*l*. It is hoped that a large portion and perhaps all of this may be secured by national legislation in the States of Europe and America that are interested in this subject.

IT is announced in *Science* that Mr. Charles H. Senff has given 5000 dollars to the zoological department of Columbia University for purposes of exploration and publication. Mr. Harrington and Mr. Sumner expect, with the assistance of this fund, to make a second expedition to the Nile in search of *Polypterus*. The fund will also be used for the publication of a memoir on the anatomy of *Polypterus*, to be undertaken conjointly by Messrs. Dean, Harrington, McGregor, Strong, Herrick and Prof. Wheeler, of the University of Chicago.

THE inaugural lecture on the possibility of extirpating malaria from certain localities by a new method, delivered by Major Ronald Ross at the Liverpool School of Tropical Medicine, is published in the *British Medical Journal*. According to Major Ross's observations in India, human malaria is not conveyed by mosquitos of the genus Culex, but by members of the genus Anopheles. Species of the former genus are generally able to breed in pots and tubs of water, cisterns, wells, and drains—that is, they seem to prefer artificial collections of water of this character to natural collections, such as rainwater, puddles, and ponds. In the case of the other genus, Anopheles, however, the larvæ are scarcely ever to be found in vessels and other artificial collections of water, but only in natural ponds and puddles. But whether the dangerous mosquitos prove to be confined to the genus Anopheles or not, it appears certain that they breed in puddles, and are not of the common domestic kind. The practicability of eradicating malaria in a locality by the extermination of the dangerous mosquitos in it thus depends on a single question—Do these mosquitos breed in spots sufficiently isolated and rare to be dealt with by public measures of repression? It is to obtain information upon this subject that an expedition to the West African coast is being organised. If it can be shown by accurate investigation that all the malaria in a large town arises from a few small puddles which can be obliterated at small expense, the value of the discovery could not easily be over-estimated.

THE *Meteorologische Zeitschrift* for June contains a brief note of the results of some important observations made by Dr. J. Tuma in seven balloon ascents, for the purpose of obtaining measurements of the distribution of atmospheric electricity in clear weather, and of determining whether the balloon itself received electrical charges. The first question is of purely scientific importance, and the second is of practical interest, as lately the burning of some balloons has been attributed to electrical discharges. The observations show that the positive potential decreases with increasing height; the positive charges are, therefore, accumulated in the lower strata of the atmosphere. During the four last ascents, Dr. Tuma was unable to find that

the balloons were electrically charged. The details of the investigation were published in the *Sitzungsberichte* of the Vienna Academy in March last.

So many attempts have been made to produce photographic pictures in natural colours, that a bibliography of recent contributions to the subject is distinctly valuable. Mr. Philip E. B. Jourdain gives such a bibliography in *Photography* of June 22. His paper supplements similar bibliographies prepared by Mr. Bolas, the chief additions being a fuller account of Edmond Becquerel's work, and abstracts of two important papers by Clerk Maxwell and Lord Rayleigh on different branches of the subject. A number of processes, in addition to those known to most men of science, are described. The bibliography carries the subject to the end of 1898, so Mr. R. W. Wood's process (see p. 119) is not included.

THE property that the locus of the poles of an arbitrary plane with respect to the conics of a Steiner's surface is another Steiner's surface has been investigated by Lie, Koenigs, and Brambilla. In a communication to the *Rendiconto* of the Naples Academy (v. 4), Prof. Domenico Montesano has dealt with the following questions connected with this problem:—(1) In what relation of position are the two surfaces? (2) Whether the relation is invertible? (3) What forms are described by the double lines, the triple point, and the double tangent planes of the new Steiner's surface when the arbitrary plane is varied? In order to answer these questions, Prof. Montesano examines the correlative questions for the surface of the third order with four double points, making these depend on other more general questions relating to a surface of the third order without singularities.

IN the *Bulletin international* of the Cracow Academy, M. P. Rudski applies the well-known problem of the elastic sphere under given surface-tractions to calculate the radial displacements of the earth's surface under the weight of ice-caps. There are strong reasons for believing that during the glacial period large areas of land were submerged, which at the present time are at considerable altitudes above the sea-level, and M. Rudski's object is to test whether these displacements of the shore-line can be accounted for by the distortion of the earth due to circumpolar ice, assuming the total quantity of water on the earth's surface to be constant. M. Rudski considers the test case of uniform ice-caps extending down to latitude 60°, and he assumes the rigidity of the earth to be the same as that of steel. The deformations are different according to whether glaciation exists about one or both poles, the depressions at the poles being respectively 347·1 and 497·8 metres for an ice-cap 2000 metres thick. Moreover, with bipolar glaciation the displacement of the shore at the edge of the ice-caps is negative, while with unipolar glaciation it is positive but smaller. In either case, supposing fiords to extend inwards into the ice-caps, the shore-displacements towards the centre of the caps would be positive.

IT is well known that the influence of a magnetic field in general increases the electric resistance of the rarefied gases, except when the lines of electric and magnetic force coincide. Profs. Elster and Geitel, writing in the *Verhandlungen* of the German Physical Society, describe an experiment showing that a magnetic field has a similar effect on the conductivity imparted to air by the influence of Becquerel rays. Experiments have also been made by the same writers, showing that the observed results were not attributable to any deviation produced in the rays by the magnet, but that Becquerel rays, like Röntgen rays, possess the property of not being deflected by magnetic force.

IN the last number of the *Zeitschr. Wiss. Zool.*, Mr. L. Johann notices certain peculiar epidermal structures occurring at the base of the spines of one of the spiny dog-fishes (*Spinax niger*), which he believes to be luminiferous. They take the form of brown or black spots, which are not shining, and are situated on a dark ground. Although distinctly visible to the naked eye, they are seen better through a lens; and, owing to the nature of the skin, are more clearly displayed in the embryo than in the adult. When sectionised and examined microscopically, they are found to contain pigment. A tropical representative of the same family (*Isistius brasiliensis*) is already known to possess luminiferous properties, and the author therefore considers that the spots in the Mediterranean species have the same function. By a fortunate coincidence, as his paper was passing through the press, Mr. Johann received a communication from Dr. Beer, of the Zoological Station at Naples, stating that a specimen of *Spinax niger* had recently been captured and brought to the aquarium there. Although wounded and in a generally feeble condition, it emitted a distinct luminosity, which would doubtless have been stronger had the fish been in robust health. The author's conclusions as to the function of the dermal spots are, therefore, demonstrated by actual experiment to be correct.

STUDENTS of the Batrachians will be much interested to read in the *Proc. U.S. Nat. Mus.* Dr. Stejneger's account of the discovery of a North American representative of the family of disc-tongued frogs (*Discoglossidae*), hitherto supposed to be confined to the northern half of the Old World and New Zealand. The determination rests on a single specimen discovered in the western portion of Washington State, which is considered to belong to a new generic type (*Ascaphus*).

THE July number of the *Century Magazine* contains an exceedingly well-written and well-illustrated article describing a rocky islet in the Gulf of St. Lawrence known as "Bird Rock," and now utilised as a lighthouse station. From the accounts of early visitors to the rock (among whom was Audubon) it appears that the number of sea-birds—such as gannets, guillemots, puffins, razorbills and petrels, with which it was covered—was almost incredible, Dr. Bryant, who paid a visit in 1860, estimating the number of gannets alone at one hundred and fifty thousand. Although, to one who has not read the old accounts, the rock would even at the present day appear a marvellous example of the exuberance of bird-life, it is only too certain that unchecked plunder of the eggs and destruction of the adults are steadily tending towards the extermination of the feathered hosts. By all means, therefore, let the Government concerned forthwith take the simple steps suggested by the author as essential to ward off the occurrence of such a dire calamity.

THE useful series of "Manchester Museum Handbooks" has received an important addition in the form of an "Index to the *Systema Naturae* of Linnæus," by Mr. C. D. Sherborn. Needless to say, this work is executed with the thoroughness and care characterising all the efforts of its author. Whether, however, it will "help in bringing about that uniformity of nomenclature which is the great need of zoological science at the present day," the future alone will show. There may also be two opinions as to whether Linnæus, the founder of our nomenclature, "had no more power to alter a name once founded than has any other person."—The "Guide to the Natural History Collections" in the same series is so well written, and contains such a large amount of information in such a very small compass, that it will prove useful to many besides actual visitors to the museum.

SLOWLY but surely is our information as to the former extension of the range of the Saiga antelope of the Volga steppes tending towards completeness. The latest addition to the remains of this animal is a skull from the superficial deposits of Kulm, recently added to the museum at Dantzic. This specimen, which has been identified by Dr. A. Nehring, is the second hitherto obtained in Germany. As our readers may remember, an imperfect skull was dug up a few years ago near Twickenham.

To the last number of the *Proceedings* of the Royal Physical Society of Edinburgh Messrs. W. S. Bruce and W. Eagle Clarke communicate a paper on the mammalia and birds of Franz-Josef Land. That such a desolate region would have but few land mammals was only to be expected, and the Polar bear and Arctic fox are the only two actually met with, although there are reports as to the occurrence of a hare, and the reindeer is represented by accumulations of its antlers, which were probably carried to their present position years ago by ice-floes. On the other hand, the birds number at least two-and-twenty species.

MR. F. TURNER reprints, from the *Proceedings* of the Australasian Association for the Advancement of Science, a paper on the supposed poisonous plants of South Australia.

THE most recent numbers received of the *Biologisches Centralblatt* contain a continuation of Dr. Keller's useful epitome of the results of recent researches in vegetable physiology and biology, as well as several original papers in different departments of zoology and botany.

WE learn, from an article in the *Board of Trade Journal* for June, that the source of the india-rubber exported from Peru through Pará has been determined by M. Hubert, a botanist on the scientific staff of the Museum of Pará, to be a species of *Castilloa*, possibly identical with the *Castilloa elastica* of Central America.

THE *Transactions* of the British Mycological Society for 1897–1898 contain several interesting papers on British Mycology, but some of them are (admittedly) reprints, and, with regard to the others, there is no information as to the date or place where they were read, or even any note of the meetings of the Society. No date even is given to the delivery of the "President's Address." The officers of the Society appear to be a President, an "Acting President," and an Honorary Secretary and Treasurer.

WE have received vol. i. No. 3 o. the Communicaciones del Museo Nacional de Buenos Aires. It contains a paper on the Coleoptera of Tierra del Fuego, and some short articles on botany, geology and nomenclature.

AN important paper, by Dr. Philip P. Calvert, on Odonata from Tepic, Mexico, with supplementary notes on those of Baja, California, has appeared in the *Proceedings* of the California Academy of Sciences (third series, Zoology, vol. i. No. 12). Detailed descriptions are given of many of the species.

THE thirteenth volume (new series) of the *Geographical Journal*, containing the six numbers of the *Journal* issued this year, has just been published. The papers printed in the volume; the record of geographical events and investigations; and the monthly bibliography of current geographical literature, make the volume, like previous ones, essential to the library of the student of geography.

THE second part of the first volume of the *Annals* of the South African Museum has reached us. Among the papers included in it are: a descriptive list of the rodents of South Africa, by Mr. W. L. Sclater; a further contribution to the South African Coleopterous fauna, by Mr. L. Péringuey; the South African species of Peripatidæ in the collection of the South African Museum, by Dr. W. F. Purcell; and a description of a new genus of Perciform fishes from the Cape of Good Hope, by Mr. G. A. Boulenger, F.R.S.

A THIRD edition, considerably enlarged, of "Metal-Plate Work," by Mr. C. T. Millis, has been published by Messrs. E. and F. N. Spon, Ltd. The volume shows how nearly all the patterns required by sheet-metal-workers can be set out on general geometrical principles. The book has proved of great value to pattern-makers since it was first published twelve years ago, and as the system of construction set forth in it is now regarded as the best means of making the practical man familiar with the geometrical principles underlying his work, the volume should be even more widely used in the future than it has been in the past.

THE additions to the Zoological Society's Gardens during the past week include a Common Paradoxure (*Paradoxurus niger*) from Java, presented by Mr. J. Osborne; a Barbary Mouse (*Mus barbarus*) from Barbary, presented by Miss Lyell; a Cormorant (*Phalacrocorax carbo*) from Scotland, presented by Mr. Percy Leigh Pemberton; two Carrion Crows (*Corvus corone*) British, presented by Lieut.-Colonel Vilett Rolleston; a Rock Thrush (*Monticola saxatilis*), European, a Yellow Hangnest (*Cassicus persicus*) from South America, presented by Mr. H. J. Fulljames; twelve African Walking Fish (*Periopthalmus koelreuteri*) from West Africa, presented by Dr. H. O. Forbes; a Brown Mouse Lemur (*Chirogaleus milii*), two Elegant Galidias (*Galidia elegans*) from Madagascar, a Red-bellied Tamarin (*Midas labiatus*) from the Upper Amazons, two Mexican Conures (*Conurus holochlorus*) from Mexico, a Tabuan Parrakeet (*Pyrrhulopsis tabuensis*) from the Fiji Islands, deposited; a Wapiti Deer (*Cervus canadensis*, ♂), a Great Eagle Owl (*Bubo maximus*), bred in the Gardens.

## OUR ASTRONOMICAL COLUMN.

COMET 1899 *a* (SWIFT).—This comet, after passing perihelion, showed such a definite increase of brightness and other evidence of internal action, that its progress was closely watched at several observatories (*Astronomical Journal*, No. 464, vol. xx. pp. 60–61). Prof. E. E. Barnard, observing it on May 20 and several succeeding occasions, with the 40-inch refractor of the Yerkes Observatory, found the head of the comet to be distinctly *double*, the smaller component being *south preceding* with reference to the main body. From successive measures it was found that the position angle was gradually decreasing, while the distance between the two nuclei was increasing from 28″·84 on the 20th to 38″·16 on the 23rd. Though no tail was visible to the eye, a photograph obtained on May 18 showed a slender tail 6° or 8° long.

Prof. C. D. Perrine also secured several observations with the 36-inch Lick refractor, confirming the duplex character of the head of the comet. The two nuclei were estimated to be of the 8·0 and 9·5 magnitude respectively, and neither appeared stellar with power of 270.

The following continued ephemeris is given by Dr. A. Stichtenoth in *Astr. Nach.* (Bd. 149, No. 3574):—

*Ephemeris for 12h. Berlin Mean Time.*

| 1899. | R.A. h. m. s. | Decl. ° ′ | Br. |

MAXIMA OF MIRA.—Mr. A. A. Nijland, of Utrecht, communicates to *Astr. Nach.* (Bd. 149, No. 3576) an account of his observations of Mira during the apparition in 1898. During the period extending from August 9, 1898, to March 5, 1899, sixty-one observations of magnitude were obtained. The light curve being plotted from these gives the time of maximum as October 4, 1898, this being very close to the predicted time given by Chandler in his third catalogue. The following table shows the observed and calculated times of the last three maxima:—

| Observed maximum. | Calculated Chandler III. | Retardation. Days. | Magnitude. | Period. Days. |
|---|---|---|---|---|
| 1897 Jan. 11 | 1896 Dec. 13 | 29 | 3·70 | |
| 1897 Nov. 26 | 1897 Nov. 9 | 17 | 3·24 | 319 |
| 1898 Oct. 4 | 1898 Oct. 6 | −2 | 2·91 | 312 |

THE NEW ALGOL VARIABLE IN CYGNUS.—Harvard College Observatory *Circular* (No. 44) contains the results of a detailed examination of all the Draper memorial plates covering the region of the variable star BD + 45°·3062, discovered by Mdme. Ceraski at Moscow (see NATURE, vol. lx. p. 114). Altogether 195 plates show the star, on 170 of which it is at its full brightness, while 20 show it below its normal magnitude. A full discussion of these plates resulted in the determination of the period of the variable to be

4d. 13h. 45m. 2s.
